

# **Insurers as Asset Managers and Systemic Risk**

**Andrew Ellul, Pab Jotikasthira, Anastasia Kartasheva,  
Christian Lundblad, and Wolf Wagner**

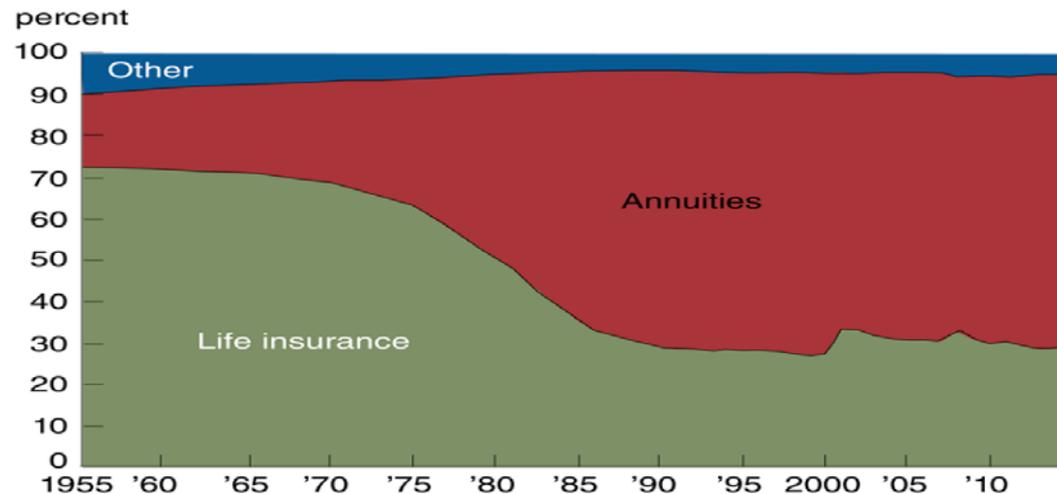

**ABFER 6<sup>th</sup> Annual Conference  
Singapore  
MAY 2018**

# Research Motivation I

- **Systemic risk can arise from the interconnectedness** of institutions.
  - ▣ Substantial evidence on the liability/funding side (mostly from banking)
  - ▣ Small, but growing evidence on **the asset side**.
    - Acharya and Yorulmazer (2007, 2008): “Too many to fail” guarantees leading to herding in asset holdings.
    - Greenwood et al. (2015): Fire sales can create contagion spreading across banks holding the same assets.
  
- **This paper**: Proposes a **new mechanism** through which financial institutions’ business commitments induce (a) reaching for yield, and (b) asset interconnectedness, leading to systemic risk.
  - ▣ New mechanism: **Shared business model**.

# Research Motivation II

- Our laboratory: **U.S. life insurers writing Variable Annuities (VAs)** = Asset managers but with caveats.

Sources: American Council of Life Insurers, *2015 Life Insurers Fact Book*, and authors' calculations.

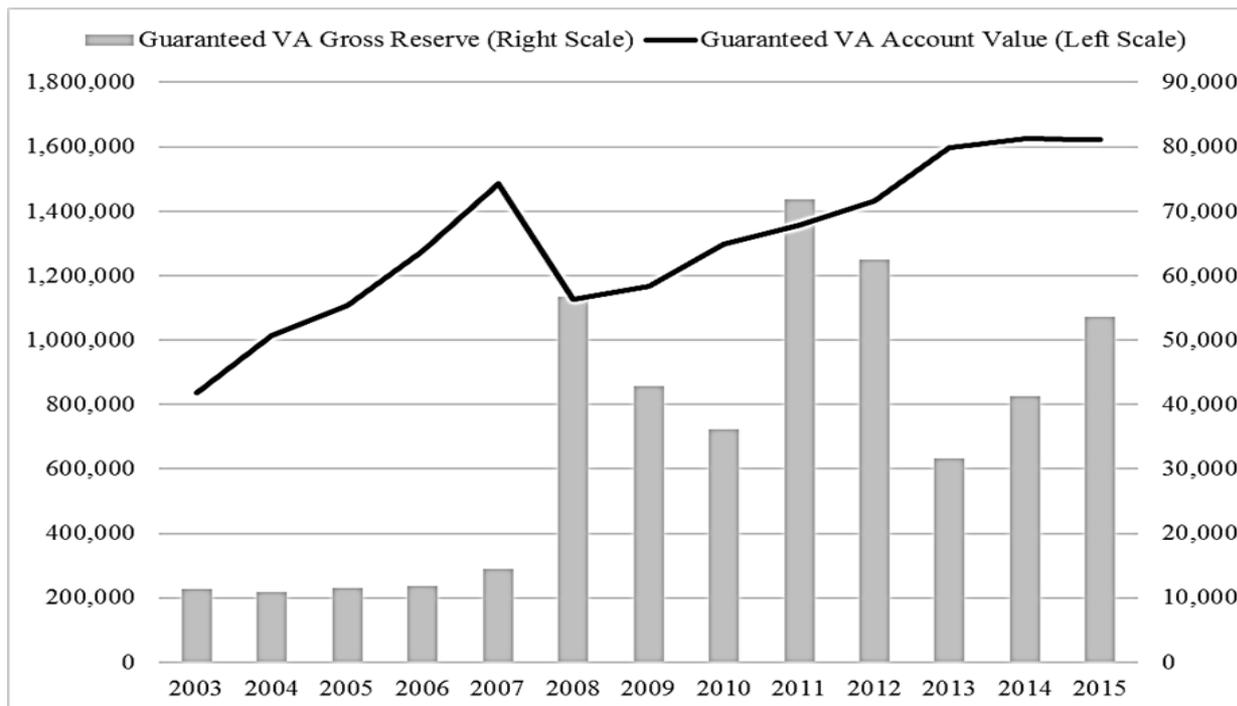

- VAs embed **guarantees**, exposing insurers to **common, undiversifiable shocks**. Hedging the guarantees leads to **correlated asset portfolios**.
- Guarantees are common for financial institutions, e.g. Defined Benefit pension plans, Banks' securitization arrangements.

# Variable Annuities

- A **Variable Annuity** is a long-term retirement saving contract between an insurer and a policyholder.
  - The fund is invested in stocks (> 70%), bonds, and money markets.
- An insurer allocates policyholder savings to a **separate account** and acts as a delegated asset manager of policyholder's funds.
  - Just like mutual funds, policyholder bears the market risk.
- **To reduce market risk** and compete with other savings alternatives, insurers offer **a host of guarantees**.
  - An assurance the policyholder's savings and annuity payments are protected from adverse market conditions, e.g. Guaranteed minimum income benefit.

# Guarantees and Insurer's Capital

- **Guarantees = Put options.** Insurers are required to hold:
  - **Statutory reserve** to ensure promised payments.
  - Plus, additional **Risk-Based Capital (RBC)** to absorb extreme losses.
- Both reserves and RBC spike during stress periods.

# Our Thesis: Guarantee → Systemic Risk?

- Traditional life policies expose insurers to “diversifiable” risk, while VAs expose them to “systematic” risk.
  - ▣ The two most important factors that influence VA-related reserves are **stock prices (and volatilities)** and **interest rates**.
- To mitigate the risk and to avoid having to raise capital during market downturn, insurers **hedge their market exposures** using both comprehensive hedging (options) and **delta hedging programs**.
- However, hedging is costly. Insurers **only partially hedge** and engage in “**reaching for yield**” to offset the hedging costs and make up the increase in reserve.
  - ▣ Reaching for yield often involve **illiquid assets**, which may propagate shocks across the financial system through **fire sales**.

# Framework of Analysis

- Build a model to analyze our hypothesized mechanism through which VAs with guarantees give rise to systemic risk:
  - Hedging engenders **correlated investment decisions** across life insurers during normal periods.
  - Asset shocks induce **correlated liquidation** during stress periods to meet regulatory reserve/capital requirements.
- Calibrate the model to U.S. life insurance data and obtain estimates of **VA-induced correlated investments** in (a) liquid bonds, (b) illiquid bonds, and (c) equity, and **price impacts** due to correlated liquidation during distress periods.
  - Fire sales may erase up to **20-70% of insurers' capital**.

# Key Elements of the Model

- A risk neutral insurer with total assets  $A$  and equity capital  $E$ .
  - ▣ Chooses portfolio to maximize expected return.
  - ▣ Three assets: Liquid bond ( $L$ ), Illiquid bond ( $I$ ), and Stock ( $S$ ) with returns  $r_L = 0 < r_I < r_S$
  - ▣ Portfolio weights denoted by  $(\alpha_L, \alpha_I, \alpha_S)$ .
  
- Two constraints:
  - ▣ Hedging: Insurer hedges a fraction  $h$  of its effective stock market exposures, induced by the guarantee → **Overweight bonds/Underweight stocks.**
  - ▣ Capital: Insurer faces risk-based capital requirement, and must keep its RBC ratio of at least  $\rho$ . → **Tilt towards illiquid bonds as permitted by capital.**

# Hedging and Capital Constraints

- Insurer writes a total amount of guarantee:  $gA$ . The underlying asset is stock (77% of VAs in reality).
- Generosity of guarantee: When stock goes down by 1 unit, the value of guarantee increases by  $|\delta|gA$ .

→ Hedging:  $\alpha_L + \alpha_I \geq h \cdot |\delta|g$

- Insurer faces fair capital charges (risk weights)  $(\gamma_L, \gamma_I, \gamma_S)$  that ignore illiquidity costs:  $\frac{\gamma_I}{r_I} = \frac{\gamma_S}{r_S}$  and  $\gamma_L = 0$

→ Capital:  $\frac{E}{(\alpha_I \gamma_I + \alpha_S \gamma_S)} \geq \rho$

# Optimal Portfolio Choice

- Under certain assumptions, both constraints are binding:
  - Insurer has to invest in **bonds** at least:  $\alpha_L + \alpha_I \geq h \cdot |\delta|g$
  - The remainder is invested in stocks:  $\alpha_S^* = 1 - h \cdot |\delta|g$
  - Within bonds, insurer **over-weights the illiquid bond**:

$$\alpha_I^* = \left[ \frac{E}{\rho A} - (1 - h \cdot |\delta|g)\gamma_S \right] \frac{1}{\gamma_I}$$

- Larger guarantee exposure  $|\delta|g$  will lead to smaller holding of stock  $\alpha_S^*$  and larger holding of illiquid bond  $\alpha_I^*$ :

$$\frac{\partial \alpha_S}{\partial |\delta|g} = -h < 0 \quad \text{and} \quad \frac{\partial \alpha_I}{\partial |\delta|g} = h \frac{\gamma_S}{\gamma_I} > 0$$

# Data

- NAIC data obtained through SNL Financial.
- 176 Life insurers (groups and stand-alone insurers) over the period 2004-2013.
  - ▣ Insurers with VA guarantees: 82 entities
  - ▣ Matching insurers without VAs, with asset size of at least the 5<sup>th</sup> percentile of insurers with VA.
- VA information: Account values, Gross reserves, Reinsurance credits
- NAIC Schedule D: Portfolio year-end positions (corporate bonds, ABSs, mortgages, etc.)
- NAIC Schedule DB: Derivatives positions.

# Insurers' Characteristics

- Insurers with high VA exposures are generally larger than others both in terms of assets (in the general account or on balance sheet) as well as capital and surplus
- Insurers with no VAs are the smallest, despite our attempt to match by asset size.

# Preliminary Evidence II

- Insurers with **high VA exposures** have **a significantly higher allocation to illiquid bonds** and **a significantly lower allocation to stocks** than do both insurers with low or no VA exposures
- Summary statistics for the asset allocations are generally consistent with our model's predictions

# Inferring Effective Guarantee Exposures

- Our goal is to estimate the sensitivity of portfolio allocation to guarantee exposure  $|\delta|g$  (which is a function of the hedge ratio in our model).
- But, we do not observe  $|\delta|g$ , only  $g$  and its associated reserve.
- Assuming that change in reserve is  $-r_S \cdot |\delta|g$ , we can use **the law of motion** to infer  $|\delta|g$ .

$$\frac{\text{reserve}_t}{\text{value}_t} = \frac{\text{reserve}_{t-1} + \boxed{\delta_{t-1} \cdot \text{value}_{t-1}} \cdot \text{ret}_{\text{stock},t-1,t} + \text{newreserve}_t}{\text{value}_{t-1} \cdot (1 + \text{ret}_{t-1,t}) + \text{newvalue}_t}$$

- We also assume that (i) 77% of account value as stocks as an underlying (23% money markets), and (ii) reserve generosity is about the same over time.

# Guarantees and Portfolio Allocation

- A one standard deviation increase in normalized delta is associated with an **increase in illiquid bond allocation of 9%**, decrease in liquid bond allocation of 5.6%, and **decrease of common stock allocation of 3.3%**.

# Implied Hedging and Capital Constraints

- Insurers hedge overall about 75% of their guarantee exposure, of which **70% is delta hedging** and **5% is in the form of options**
- Given a capital requirement of 0.30 for common stock, the estimated capital requirement for illiquid bonds is 11.3%

**Test of over-identifying restrictions**

# Counterfactual Portfolios

- Portfolio allocation is driven by two factors
  - ▣ Hedging of guarantee exposure: tilt the allocation to bonds
  - ▣ Reaching for yield: tilt the bond allocation to illiquid (riskier) bonds
- **Hypothetical Portfolio 1**: Actual – Port 1 = “reaching for yield”
  - ▣ Keep total bond allocation the same as actual (= same VA exposure and same hedge ratio), but
  - ▣ “Re-allocate between” liquid and illiquid bonds such that the ratio of their allocations is as if the insurer had no VAs.
- **Hypothetical Portfolio 2**: Port 1 – Port 2 = “partially exposure to guarantees”
  - ▣ Set the normalized delta to zero (= no VA exposure and no hedging).

# Guarantees and Systemic Risk

- With some probability, a common shock may hit.
- What is the impact of a shock on fire sales, and how much is attributed to VAs?
  - ▣ Stock market shock, and shock to illiquid bonds
  - ▣ Shock to the guarantee, e.g., increase in stock market volatility.
  - ▣ Categorical asset shock, proportional reduction in values of all assets.
- **A shock reduces capital** by lowering asset values and increasing the guarantee liability.
  - ▣ Deleverage by selling assets proportionally (as in Greenwood et al. 2015).
  - ▣ Stocks and liquid bonds are sold at fair value; **illiquid bonds face a discount of  $c_0 S$** , where  $S$  is the total sales of illiquid bonds by all insurers.

# Equilibrium Level of Fire Sales

- From the capital requirement constraint, derive the amount of **sales** by an individual insurer:

$$s = \frac{\varepsilon}{(\varepsilon + \alpha_I \cdot c_0 S)} \frac{A - E}{E}.$$

**Shock as fraction of A**

- With a collection of insurers, each denoted by  $i$ , total **equilibrium sales** are as follows:

$$S = \frac{\varepsilon \sum_i \frac{A^i - E^i}{E^i} \alpha_I^i A^i}{1 - c_0 \cdot \sum_i \alpha_I^i \frac{A^i - E^i}{E^i} \alpha_I^i A^i}.$$

- We measure total fire sale costs, **our measure of systemic risk**, as

$$C = S \cdot c_0 S$$

# Stock Market Shock

- Stock market shocks 10-40% → insurers selling \$114-458 billion of illiquid bonds → **fire-sale costs = \$2-39 billion = 1-21% of insurers' total capital**
- Without VAs, the sale amount = \$50-201 billion → **fire-sale costs = \$0.5-7.5 billion**

|                    | Fire-Sale Amount (\$ Million) |                          |                          |                      | Decomposition of Fire-Sale Amount (\$ Million) |                            |                          |

# Shock to Illiquid Bonds

- Shocks to illiquid bonds of 2-8% (proportional to capital requirement, relative to stock market shocks of 10-40%) would result in actual insurers **selling \$107-\$431 billion of illiquid bonds**.
- The fire-sale costs are **1%-19%** of insurers' total capital

# Categorical Shock

- Categorical shocks to all assets would result in insurers **selling \$236-\$943 billion of illiquid bonds**, more than the sum of each shock due to externality.
- The fire-sale costs **potentially catastrophic**. [similar to the financial crisis].

| Magnitude of Shock | Fire-Sale Amount (\$ Million) |                          |                          |                      | Decomposition of Fire-Sale Amount (\$ Million) |                            |                          |

# Shock to Value of Guarantee

- Positive shocks to the value of guarantee of 20-80% (e.g., 2011) would induce actual insurers to **sell \$115-\$459 billion of illiquid bond**.
- These effects are exclusively due to the VAs, by construction.
- The costs associated with these fire sales are **\$2-\$39 billion**, of which about **72%** are attributed to reaching for yield.

| Magnitude of Shock | Fire-Sale Amount (\$ Million) |                          |                          |                      | Decomposition of Fire-Sale Amount (\$ Million) |                            |                          |

# Remaining Discussion Points

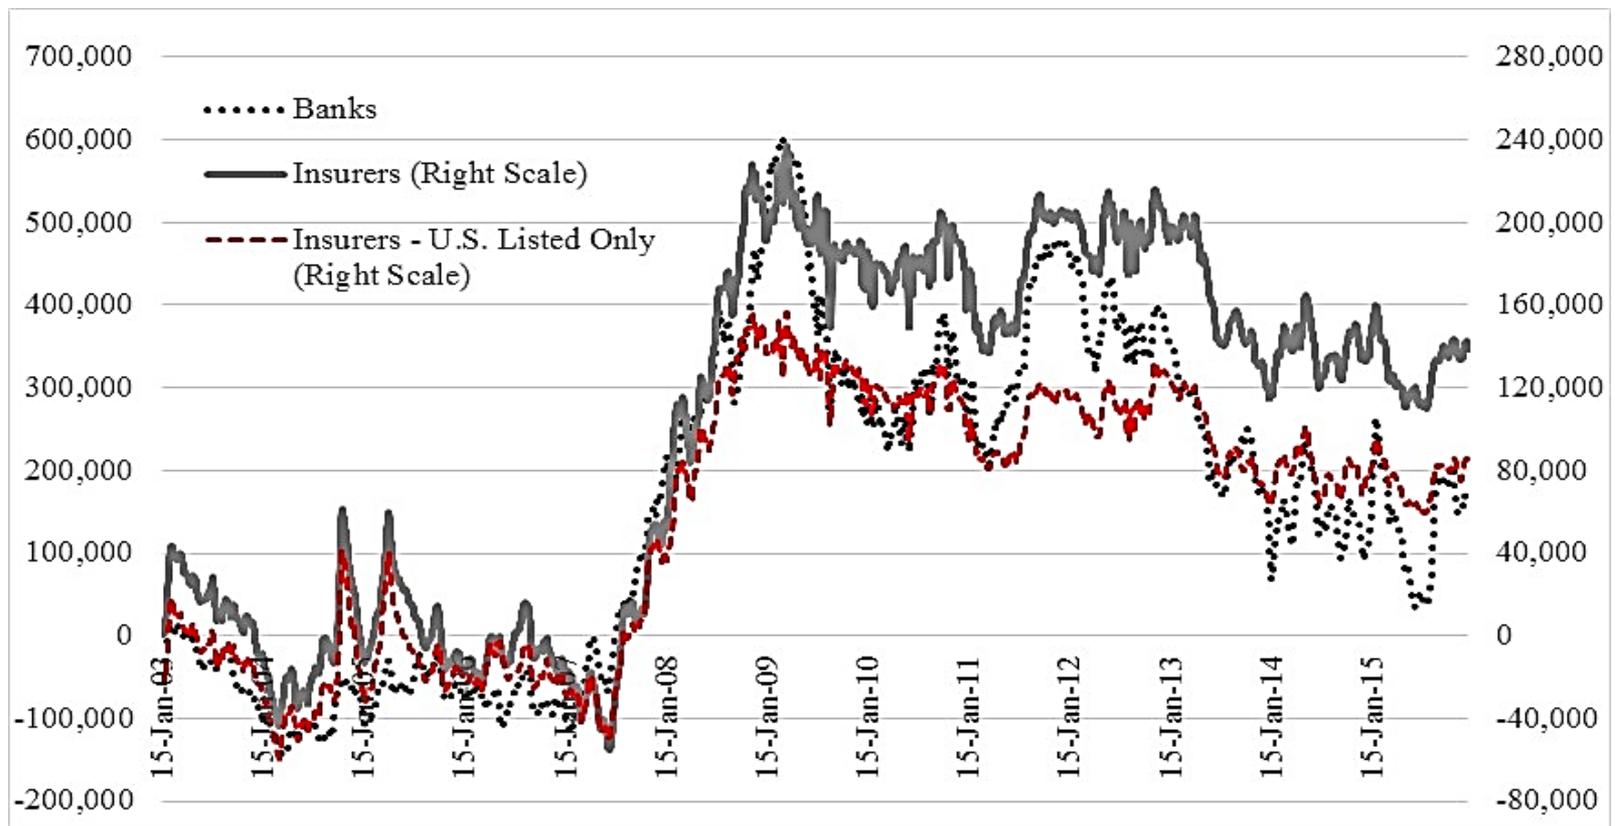

- Direct capital adequacy implications of VAs with guarantees (and other business risks)? [Appendix B]
- Delta hedging in the face of a varying delta itself.
- Accounting Treatment: HCA vs. MTM
- Spillovers outside life insurers: P&C, Banks, derivative counterparties, etc.
- Generalizability of guarantees...

# Conclusions

- Why are FIs inter-connected on the asset side?
- Propose an innovative mechanism: An incentive that arises from the financial institutions' **business model (pervasive guarantees.)**
  - ▣ A theoretical model that captures the underlying economics and then calibrate the model by using insurer-level data.
- **Correlated holdings in illiquid assets emerge in equilibrium,** raising the likelihood of fire sales in the event of common shocks.
- Message: VAs with guarantee make life insurers **less likely asset insulators** (Chodorow-Reich et al. (2017)) and **more likely contributor to systemic risk.**
  - ▣ Similar guarantees and mechanism exist in various financial institutions!

# Insurers' Systemic Risk

- Banks' systemic risk seems to have significantly decreased for individual banks and the industry...but **remains elevated for some insurers**

# Insurers and Recent Equity Market Turmoil

## Why insurers are being blamed for equity market instability

FT 22/02/2018

Market strategists and industry analysts say a post-crisis change to the way US life insurers manage billions of **customer dollars invested in variable annuities (VAs) has been a primary source of the instability**. ... For the companies that remained in the business [after the crisis], there was a need to find a way to meet demand for such guarantees while avoiding a rerun of the crisis. In 2011 the VA industry introduced managed volatility funds, also known as “target vol” funds. ... The recent market swoon happened at a time when the economic fundamentals were solid. **Some analysts fret that the more fuel these funds pour on the fire, the more damaging it will be when markets are contending with a bigger conflagration.**

## Wall St blames turmoil on insurers' volatility strategy

FT 14/02/2018

Wall Street is pointing the finger at **insurance companies as an unlikely but pivotal source of the turbulence** that wiped trillions of dollars off stock market values in recent days. .. strategists and investors said **a significant portion of the selling could be traced to variable annuities**, a popular tax-advantaged insurance company product that offers customers guaranteed returns.

# VAs with Guarantees

## □ Guaranteed minimum death benefit (GMDB)

- Policyholder purchases \$150,000 variable annuity and selects a GMDB. Following poor capital market performance, the value of the account is \$75,000 in 10 years. A policyholder dies in year 10 of the policy. Beneficiary receives \$150,000

## □ Guaranteed lifetime withdrawal benefit (GLWB)

- Policyholder purchases \$150,000 variable annuity and a GLWB of 4% annually. Following poor capital market performance, the value of the account is \$75,000 in 10 years. Policyholder is in a good position though because she will receive \$6,000 ( $4\% \times 150,000$ ) for lifetime; the lifetime income is guaranteed and not limited to \$150,000

## □ Guaranteed minimum income benefit (GMIB)

- Policyholder purchases \$150,000 variable annuity and selects a GMIB that provides 4% annually. Following poor market performance, the variable annuity contract value is only \$75,000 at the end of 10 years. But a policyholder has \$222,036 to annuitize as a result of the GMIB

# VAs with Guarantees

## □ Guaranteed minimum withdrawal benefit (GMWB)

- Policyholder purchases a \$150,000 variable annuity and selects a GMWB that provides 4% annually. Following poor capital market performance, the variable annuity contract value is only \$75,000 at the end of 10 years. A policyholder is in a good position though because she will receive \$6,000 ( $\$150,000 \times 4\%$ ) per year until the \$150,000 is recovered

## □ Guaranteed minimum accumulation benefit (GMAB)

- Policyholder purchases a \$150,000 variable annuity and selects a GMAB. Following poor capital market performance, the variable annuity contract value is only \$75,000 at the end of 10 years. A policyholder is in a good position though because the variable annuity contract value is still \$150,000 at the end of 10 years

# Without Reaching for Yield

- Portfolio 1, on average, allocates 0.109 less to illiquid bonds and 0.109 more to liquid bonds → Effects of reaching for yield.
- Compared to the portfolio of insurers with no VAs, Portfolio 1 allocates 0.045 less to common stocks, reshuffling that amount to liquid and illiquid bonds

# Without Guarantee Exposures

- Portfolio 2 has significantly **less illiquid bonds** and **more liquid bonds and common stocks** than actual.
- By calibration, Portfolio 2 looks quite similar to the actual portfolio of insurers that do not write VAs.
