Does Financial Globalization Propagate Managerial Skills? Lessons from the Mutual Fund Industry

Si Cheng¹, Massimo Massa², Hong Zhang³

This Draft: Apr 2018

Abstract

We examine whether financial globalization helps propagate the managerial skills of financial institutions. Using a complete sample of global mutual funds, we find that low-skilled fund companies may strategically differentiate their products by launching new funds that track less-explored foreign equity market indices. These new funds bring in asset growth to their managing companies but fail to deliver performance or diversification benefits to their investors. Moreover, their associated cross-border capital flows reduce price efficiency and liquidity in the target country, suggesting that globalization is not necessarily accompanied by the propagation of the beneficial influence of managerial skills.

Introduction

Financial liberalization and its associated cross-border capital flows are at the heart of international finance (Karolyi and Stulz, 2003). Economists and regulators, however, are widely divided over its policy implications. For instance, the former chairman of the U.S. Federal Reserve, Alan Greenspan, stated that the "globalization of finance" has patently contributed "to ever higher standards of living around the world".¹ Indeed, vast evidence shows that a market's opening to foreign investors can be beneficial to the local economy by reducing the cost of capital (Bekaert and Harvey, 2000), increasing real investment (Henry, 2000), spurring growth (Bekaert, Harvey, and Lundblad, 2005, 2009), and providing a better process of global information (Bae, Ozoguz, Tan, and Wirjanto, 2012). In contrast, others question whether the financial liberalization process has gone too far and harmed the global market in certain scenarios (e.g., Jotikasthira, Lundblad, and Ramadorai, 2012; Hau and Lai, 2017). Nobel laureate Joseph Stiglitz (2013) even argued that "the instability in cross-border capital flows has been particularly troublesome" for—although not limited to—emerging markets.² It is puzzling to see that the same cross-border capital flows trigger such drastically different opinions.

This paper aims to shed new light on this debate by exploring the micro-foundations and incentives underlying cross-border capital flows. In this era of financial globalization, all cross-border capital flows are not the same in these dimensions. Take the global mutual fund industry, which manages trillion-dollar cross-border capital flows, as an example. On one hand, its globalization process can promote investor welfare and financial efficiency by allowing more skilled mutual fund companies (or interchangeably, mutual fund families) to manage more capital. On the other hand, however, the same globalization process may also provide an opportunity for some low-skilled fund companies to survive, if not thrive, in the global market. Cross-border flows associated with the latter type of globalization may not improve investor welfare or market efficiency; indeed, they may be harmful. If so, it will be crucial to understand the (potentially heterogeneous) economic foundations of foreign capital flows in order to reconcile opposing views on capital flows and to discuss related policy implications.

But how can globalization, which hypothetically should enhance competition and thus the expansion of high-skilled funds, enable the proliferation of low-skilled fund companies? Our intuition stems from two strands of studies. The first recognizes that mutual funds, similar to non-financial companies, compete for investors' capital flows via prices (e.g., reduced mutual fund fees in Wahal and Wang, 2011) or product differentiation (e.g., in terms of the degree of active management in Cremers, Ferreira, Matos, and Starks, 2016). The second strand notes that to the extent that investors

often invest according to style strategies (e.g., Mullainathan, 2002; Barberis and Shleifer, 2003; Barberis, Shleifer, and Wurgler, 2005), index-linked investment plays an especially important role in our economy (Boyer, 2011; Wurgler, 2011). These features may allow a global fund company to adopt index-based product differentiation—i.e., to launch new products (funds) that trace relatively less-explored global indices—as its growth strategy. When new indices either emerge in a country as a result of financial development or open to foreign investment due to financial liberalization, for instance, this company can launch new funds tracking such indices, sell these funds as new products to global style investors, and achieve growth. When there is no confusion, we label this index-based strategy a *catering strategy* in the spirit of Baker and Wurgler (2004a and 2004b) to emphasize that it aims to attract capital by exploiting investors' demand for style investment rather than by pursuing and delivering superior performance.

To illustrate the potential existence of index-based growth strategies in practice, we plot the number of major stock market indices explored by the global mutual fund industry (i.e., traced by at least ten mutual funds) in Figure 1. This number has increased drastically from 130 in 2000 to 440 in 2009, consistent with Wurgler's (2011) observation that the number of indices reported in *The Wall Street Journal* has grown exponentially in the past century. More interestingly, this growth in indices has been accompanied by a similar growth in both the number of funds and the value of assets under management. This latter pattern, while ignored thus far in the mutual fund literature, strongly suggests that some sort of index-based growth strategies might have been explored by the global mutual fund industry.

Although the catering strategy specifies one explicit mechanism through which low-skilled companies may attract capital, both the scale of its presence and the scope of its influence are subject to the competition vis-à-vis high-skilled companies. In particular, high-skilled companies may have incentives to seek alphas in less-explored foreign stocks. If high-skilled companies can consistently launch new funds investing in foreign markets and subsequently deliver superior performance, they are likely to dominate overseas expansions in the long run, creating a winner-takes-all equilibrium. We refer to this scenario as the *winner-takes-all high-skill expansion hypothesis* or simply the *high-skill expansion hypothesis*. Overseas expansions of mutual fund families in this scenario are associated with the propagation of managerial skills and fund performance.

However, when skills are largely country-specific or when high-skilled companies face decreasing returns (e.g., Berk and Green, 2004) in deploying their ability in different countries, for instance, due to increasing transaction and information costs, high-skilled companies may want to focus on domestic alpha strategies rather than pursuing global alpha strategies. In this case, the incentive for high-skilled companies to participate foreign markets is reduced by such market frictions. Low-skilled fund companies can use this opportunity to specialize in catering-oriented globalization strategies and thrive by attracting global style investors to invest in their new funds. This "separating

equilibrium" (call it the *catering-oriented low-skill expansion hypothesis*) therefore predicts a negative relationship between the overseas expansions of fund companies and their skills/performance.³

Finally, while high-skilled companies' skill in delivering alpha could be largely jeopardized by friction in foreign markets, nothing prevents them from adopting catering-oriented globalization strategies to launch foreign funds. Different from the *high-skill expansion hypothesis*, however, these new funds are not associated with superior performance. In this interesting scenario, both high-skilled and low-skilled fund companies adopt similar catering strategies. It is not easy to predict which type of company could benefit more from globalization in the long run, as the answer depends on whether catering-based globalization strategies and skill-based alpha strategies can generate synergy for high-skill companies. However, one unambiguous and fundamental feature of this scenario is that *catering-oriented* overseas expansion does not depend on the skills of fund companies because the strategy is adopted by both high- and low-skilled companies. For this reason, we refer to this scenario as the *irrelevance hypothesis* when there is no confusion.

The above hypotheses pave the way for us to understand the incentives and consequences of foreign capital flows. In particular, the influence of foreign capital flows on investor welfare and market efficiency differs drastically in these different scenarios. Both investor welfare and market efficiency are likely to decrease in the *low-skill expansion hypothesis* because a significant amount of capital is channeled to foreign markets by less-skilled fund companies. More capital flows of this type are likely to result in a lower degree of informational efficiency (because corresponding fund companies have relatively low information-processing skills) and lower liquidity (because these companies lack the incentive or skills to trade) and are unlikely to deliver the benefits of financial liberalization documented by the literature. Both investor welfare and market efficiency, however, are likely to increase in the case of the *high-skill expansion hypothesis*. The welfare and efficiency implications of the *irrelevance hypothesis* are similar to those of the *low-skill expansion hypothesis*. The two hypotheses can be differentiated based on the characteristics of companies that make catering expansions.

We test these competing hypotheses by focusing on the complete sample of actively managed global open-end mutual funds over the period from 2001 to 2012. Our empirical analysis consists of three steps. The first step aims to measure catering incentives and to assess the extent to which such incentives prevail in cross-border expansions. We measure the *catering incentive* of investing in a target country (i.e., to launch a fund tracing the country's equity indices) by the *number of unexplored indices* therein—i.e., the total number of indices in that country tracked by domestic funds that are not

³ Investors' demand for style investment provides a necessary condition for funds to adopt catering-oriented strategies. Why investors have such a preference, as style preference in general imposes a constraint on performance, remains an open question.

yet invested in by any foreign funds. As this number increases, the country becomes more attractive in catering-oriented cross-border expansions because more "new products" can potentially be launched that loosely track those indices.

We find that the likelihood of launching a cross-border expansion in a target country is significantly positively associated with this number: among all the foreign countries into which global fund companies can potentially expand, one additional unexplored index in a particular country increases the probability for some foreign fund companies to launch a new product there in the next year by 20%. In this regard, it is a common practice for fund companies to launch new funds to exploit unexplored foreign indices—i.e., to conduct catering-oriented overseas expansions. Summary statistics further show that fund companies conducting more catering-oriented expansions deliver lower returns, charge lower fees, and trade less; in addition, they achieve asset growth more from launching new funds than from attracting flows to existing funds. Though descriptive, these features suggest that globalization in the mutual fund industry may not be associated with the propagation of skills as a first-order effect.

In the second step of our analysis, we formally investigate the performance and investor welfare of catering-oriented cross-border expansions. We start by examining the five-year (Fama-French-Carhart four-factor adjusted) performance of the newly launched foreign funds and find it to be negatively associated with the catering incentives of those funds (as revealed by the number or rank of unexplored indices of the target country whose indices the new funds trace). A one-standard-deviation increase in the number (rank) of unexplored indices of the target country reduces the out-of-sample five-year performance of the newly launched funds by 1.43% (0.97%) per year.

Given that mutual funds are arguably better at processing local (domestic) information, a more direct proxy for the skills of fund companies is the performance of their affiliated domestic funds. Therefore, we next link the fund companies' catering incentives to their domestic funds' out-of-sample performance. The catering incentives of a fund company is quantified as the *average* number (or rank) of unexplored indices for *all* its cross-border expansions made in a year. A larger average number reveals a more pronounced incentive for the fund company to pursue catering-oriented cross-border expansions. We find a significantly negative relationship: fund families with higher catering incentives display lower out-of-sample performance of their domestic funds. The performance difference (four-factor-adjusted) between fund families with low and high catering incentives can be as high as 2.8% per year. These observations lend support to the *low-skill expansion hypothesis* but not to the other two hypotheses.

As a robustness check, we apply the above test to all the U.S. domiciled fund families that engage in cross-border expansion. This subsample test is important because all unobservable characteristics of family domicile country are automatically controlled for. Moreover, the performance of the domestic funds offered by these families (i.e., domestic U.S. mutual funds) can also be more precisely measured by the Fama-French-Carhart four-factor model. We reach the same conclusion in this important subsample that fund families with higher catering incentives exhibit lower skills. As another robustness check, we examine the performance of all affiliated foreign funds except for newly launched ones. Again, we find that fund families with strong catering incentives underperform.

Thus far, our performance tests suggest that low-skilled fund companies are more likely to engage in catering-oriented cross-border expansions, which also deliver lower performance to investors. One remaining issue in terms of investor welfare is whether this low performance is compensated by a higher degree of international diversification. Cross-border expansions, for instance, may reduce the average correlation across funds offered by the same family, thereby allowing investors to enjoy greater diversification benefits. The data, however, tell a different story: a one-standard-deviation increase in the number (rank) of unexplored indices is associated with an *increase* in the five-year return and style-adjusted return correlation between the newly launched fund and those of existing affiliated funds by 1.35% or 2.05% (1.29% and 1.48%). In this regard, catering-oriented expansions do not seem to enhance the degree of diversification that investors can enjoy within a family. Moreover, we find such expansions do not provide a hedge against the Global Financial Crisis—i.e., these funds do not deliver a better performance during the crisis.

Our third and final analytical step investigates the market influence of low-skill cross-border expansions. We focus on three dimensions that are particularly important for cross-border capital flows: informational efficiency, liquidity, and market integration. In terms of informational efficiency, although foreign investors are typically believed to have less local information, Bae, Ozoguz, Tan, and Wirjanto (2012) show that foreign capital can nonetheless benefit emerging markets by better processing global information. To test whether catering-oriented capital flows are associated with this benefit, we treat families whose catering incentives are among the top tercile as catering-oriented fund families and examine the relation between price delay to global market information (the main variable of interest in Bae, Ozoguz, Tan, and Wirjanto, 2012) and the ownership of those catering-oriented fund families.

We find that higher stock ownership by catering-oriented foreign funds is associated with *greater* price delay to both global market information and domestic market information. In other words, catering-oriented foreign capital flows are associated with lower informational efficiency both in terms of global information and in terms of local information. To further validate this result, we also link price delay to newly launched catering-oriented cross-border funds and find a similar relationship. Since newly launched funds bring in positive changes to existing catering-oriented ownership, we can interpret this test as a way to quantify the incremental price delay associated with changes in catering-oriented ownership, which is essentially a Granger causality test of the first result.

To further alleviate potential endogeneity concerns, we follow Coval and Stafford (2007) and examine fire sales (and purchases) of catering-oriented funds. Fire sales experienced by individual funds introduce plausibly exogenous shocks into their ownership (e.g., Coval and Stafford, 2007; Jotikasthira, Lundblad, and Ramadorai, 2012; see Dow and Han, 2018 for a recent theoretical treatment on the economic mechanism of fire sales), which are unlikely to be directly related to the price efficiency of the fund investing country except through the investment behavior of these funds. Empirically, we find that fire sale flows of catering-oriented funds also influence price delay in a similar manner.

It is especially striking to see that the influence of catering-oriented foreign capital flows on global information processing is exactly the opposite of that of general foreign capital flows as reported in the literature. To reconcile our finding with the literature, we conduct additional tests and find that the impact of active cross-border capital flows that are the least related to catering incentives (i.e., non-catering families, whose catering incentives are among the bottom tercile) is indeed beneficial in processing global information. A one-standard-deviation increase in the ownership of catering-oriented foreign funds (non-catering funds) is associated with a 1.33% greater (0.84% lower) price delay with respect to global market information for all countries and a 3.63% greater (2.37% lower) price delay for emerging markets, where all numbers are scaled by the standard deviation of price delay. In this regard, catering-oriented low-skilled foreign capital flows can reduce price efficiency by 6% compared to beneficial; their influence on price delay is largely insignificant in the short run, suggesting that even funds with the proper incentives may not benefit the investing country when these funds are themselves in trouble.

If low-skilled fund companies do not improve information processing, maybe they help by supplying liquidity to the local market. To examine this potential benefit, we link the ownership of active catering-oriented foreign funds to the two main indicators of liquidity in international finance: Amihud *illiquidity* (Amihud, 2002) and the proportion of zero daily returns in a month (Lesmond, Ogden, and Trzcinka, 1999). We find little evidence of a beneficial role. By contrast, catering-oriented foreign ownership reduces liquidity, if anything. Moreover, consistent with the general role of international investors as reported in Karolyi, Lee, and van Dijk (2012), this type of foreign capital flow increases commonality in liquidity. Jointly, these results suggest that in terms of liquidity, catering-oriented foreign capital flows not only harm general liquidity conditions but also enhance contagion risk by boosting commonality in liquidity in the local economy.

Finally, we examine the potential influence of catering-oriented foreign capital flows on market integration. In line with the literature (e.g., Griffin, 2002; Fama and French, 2012; Hou, Karolyi, and Kho, 2011; Massa and Schumacher, 2015; Karolyi and Wu, 2016), we define market integration according to the absolute value of the intercept and the adjusted R-square of a regression of stock

returns on alternative factor models. As the absolute value of the intercept decreases and the adjusted R-square increases, the degree of integration increases. We find that catering-oriented foreign capital flows do not significantly increase the degree of market integration either.

Overall, our results suggest that globalization may allow low-skilled mutual fund companies to conduct catering-oriented cross-border expansions, resulting in reduced investor welfare and market efficiency. These conclusions are robust to a list of alternative tests, such as excluding closet-index funds (Cremers, Ferreira, Matos, and Starks, 2016) from the sample of active funds, using different risk factors (e.g., global and domestic factors) to compute performance, and replacing after-fee performance with before-fee performance in the spirit of Berk and Green (2004).

Although the catering mechanism we documented implies an unintended negative influence of globalization, it should not be taken as evidence against globalization. Instead, our results suggest that cross-border capital flows are heterogeneous in nature because of their different micro-foundations. One important normative implication of these findings is that optimal regulations should perhaps cater to this heterogeneity instead of relying on one-size-fits-all policies.

We contribute to several strands of the literature. To the best of our knowledge, we are the first to analyze the heterogeneity among cross-border capital flows in terms of foreign index-linked catering incentives. In doing so, we contribute to the literature on financial liberalization (e.g., Bekaert and Harvey, 2000; Henry, 2000; Karolyi and Stulz, 2003; Bekaert, Harvey, and Lundblad, 2005, 2009; Bae, Ozoguz, Tan, and Wirjanto, 2012; Jotikasthira, Lundblad, and Ramadorai, 2012; Bartram, Griffin, Lim, and Ng, 2015; Hau and Lai, 2017) by laying out a potential framework built on catering incentives (e.g., Baker and Wurgler, 2004a and 2004b) to understand the subtle impacts of cross-border capital flows.

We also contribute to the literature on competition in the mutual fund literature. While the analysis of competition is very important, our understanding of its role in the mutual fund industry remains rather limited, focusing mostly on its influences on fees (e.g., Wahal and Wang, 2011; Khorana and Servaes, 2004), product differentiation in terms of active management (Cremers, Ferreira, Matos, and Starks, 2016), and organizational structure (Massa, 2003).⁴ We extend the literature by demonstrating that the globalization of finance alters the way global mutual fund companies compete with each other. In particular, product differentiation in terms of foreign indices-linked cross-border expansions becomes feasible, which will also profoundly affect the efficiency of the global market.

⁴ Researchers also debate the degree of competitiveness in the mutual fund industry. Coates and Hubbard (2007) use the number of class action lawsuits against mutual funds to argue that mutual fund advisory fees are not what a competitive market would suggest. Berk and Green (2004) argue that mutual fund managers can grasp the economic rent of performance. Gil-Bazo and Ruiz-Verdú (2009) argue against competition, showing that the fund industry has catered to performance-insensitive investors, exploiting them by charging high fees. Hortaçsu and Syverson (2004) show that a non-competitive model of investor behavior based on search costs helps to explain price (i.e., fee) setting in the mutual fund industry.

Our study is also related to the literature on the market implications of investor demand in general and index-related style strategies in particular (e.g., Merton, 1987; Coval and Moskowitz, 1999, 2001; Grinblatt and Keloharju, 2001a and 2001b; Shapiro, 2002; Mullainathan, 2002; Barberis and Shleifer, 2003; Barberis, Shleifer and Wurgler, 2005; Boyer, 2011; Wurgler, 2011). We extend the evidence on style investment to an international setup. Indeed, our finding that catering-oriented cross-border expansions are associated with both lower performance and low diversification benefits suggests that investors are heavily influenced by styles or categories related to foreign equity market indices when making investment decisions.

The remainder of this paper is organized as follows. Section II presents our variables and summary statistics. Section III examines the baseline relationship between fund performance and catering incentives in the global mutual fund industry. Section IV reports the asset pricing implications of catering-oriented cross-border capital flows in the target market. Section V concludes.

II. Data and Main Variables

In this section, we describe our data and how we construct the main variables used in the analysis.

A. Data Sources

Our data are drawn from different sources. The main database is the Morningstar mutual fund database, which reports monthly total returns for global mutual funds. Morningstar International has complete coverage of open-end mutual funds worldwide beginning in the early 1990s. The database is survivorship bias-free, as it includes data on both active and defunct funds. The mutual fund holdings data are from the Factset/Lionshares database. The Factset/Lionshares holdings data on international funds are sparse before 2001, so our sample is restricted to the 2001–2012 period.

We match the database to the Morningstar mutual fund database. From Morningstar, we obtain additional control variables, such as management expenses, fund total net assets (TNA), fund turnover, etc. We consolidate multiple share classes into portfolios both by adding share class net assets together and by value weighting share class returns, fees and turnover ratios based on share class total net assets (TNA). More specifically, to compute returns, we obtain fund total returns net of fees. When a portfolio has multiple share classes, we compute its total return as the total net asset (TNA)-weighted return of all share classes of the portfolio, where TNA values are one-month lagged. All prices have been converted to U.S. Dollars.

We focus on active funds in our study. To distinguish index funds, we use information from Morningstar (i.e., "Index Funds"). We focus on active funds for two reasons. First, given that we study market efficiency, focusing on actively managed funds is conceptually appealing because they are supposed to process information and deliver performance. Second, most foreign funds (i.e., funds that are domiciled in one country but invest in another) that manage cross-border capital flows in the global mutual fund industry are indeed active in our sample. This feature is not surprising. On one hand, being active will not hurt the attractiveness of funds when investors make foreign-style linked investments because these funds do track foreign styles to some extent. On the other hand, being active also provides funds with leeway to escape direct competition of index replication. Since the goal of product differentiation is to escape direct competition, most catering-oriented funds are sold as "actively managed." Hence, consistent with Cremers, Ferreira, Matos, and Starks' (2016) observation that active funds outnumber explicit index funds almost eight to one in the global market, we find that more than 90% of catering-oriented cross-border expansions are self-labeled "active" in our sample.⁵

We further require funds to follow one of the major global equity indices—i.e., indices that are followed by at least ten funds—as their primary benchmark.⁶ Information about fund benchmarks comes from Morningstar ("Prospectus Primary Benchmark"). Moreover, because we must estimate fund factor loadings based on past fund returns, we require funds to have at least two years of reported returns.

The firm-level stock market data are drawn from Datastream for non-U.S. stocks and CRSP for U.S. stocks. The final sample includes 9,754 actively managed equity mutual funds (both active and dead funds) and 1,899 mutual fund families in 37 countries. Most funds come from developed countries. Among them, U.S. funds represent 75% of the sample in terms of TNA but only 37% of the number of funds. Interestingly, a total of 1,154 mutual fund families (or more than 60% of all fund families) launched new active funds outside their domicile countries during our sample period. This observation highlights the importance of the globalization of finance for the global mutual fund industry.

B. Main Variables Related to Catering Incentives

The identification of each country's major equity indices comes from Morningstar's "Primary Prospectus Benchmark ID." If the "Primary Prospectus Benchmark ID" is missing, we use the term "Primary Prospectus Benchmark." We assign to each index a domicile country based on the market in which the majority of the stocks included in the index are traded—i.e., the country in which its portfolio holding has the largest market value.

⁵ In robustness checks, we also consider the inclusion of index funds and the exclusion of closet indexing funds (e.g., Cremers, Ferreira, Matos, and Starks, 2016). Index funds may affect family performance when families strategically engage in cross-subsidization between active funds and index funds. In contrast, closet indexing funds may import errors in estimating the performance of active funds, although such errors may not be decisive given that the assets of truly active funds almost triple those of closet indexing funds. We will show in the Internet Appendix that our results are robust to these alternative samples. These robustness checks also address the potential concern that our results are driven by families that specialize in launching and managing foreign index funds and foreign closet index funds.

⁶ This request works against us in finding significant results, because some minor indices can be created for catering purposes. The latter effect of index creation, however, goes beyond the scope of the current paper.

The main variable for capturing the catering incentives for overseas expansion into a target country is the number of indices unexplored by foreign mutual funds in that country (*Num_UIT*). More explicitly, we define this variable as the total number of indices invested by domestic or foreign funds minus the number of indices invested by foreign funds in the country at any given time. Effectively, this variable measures the number of indices in the country that are invested by domestic funds but not yet invested by any foreign funds. A higher number indicates that the *country* is more attractive in terms of product differentiation and catering incentives.

A similar but alternative measure can be constructed by normalizing the numbers of unexplored indices in each country based on cross-country ranks of these numbers. More specifically, we can first rank the number of unexplored indices across countries and then normalize these ranks to follow a [0, 1] uniform distribution. This variable, which we label the "rank of unexplored indices" (*Rank_UIT*), can help alleviate any concerns related to the skewed distribution of *Num_UIT*, our main independent variable. For instance, suppose two countries have *Num_UIT* of 10 and 30, respectively; their *Rank_UIT* will be normalized as 0.5 and 1, which reduces the skewness.

To the extent that the number and rank of unexplored indices measures the catering attractiveness of a particular country, we can also measure the catering incentive of a particular fund company based on its revealed preferences—i.e., the *average* number of unexplored indices for *all* its cross-border expansions. In particular, we define the family-average number of unexplored indices, *Fam_Num_UIT*, as the average number of unexplored indices of the target countries for all cross-border funds launched by the same family in each year. A higher average number reveals a stronger incentive for the fund company to strategically launch new funds tracking less-explored indices—i.e., the incentive to pursue catering-oriented cross-border expansions—in the given period. Similarly, we define the *family-average rank of unexplored indices*, or *Fam_Rank_UIT*, as the average rank of unexplored indices.

Based on the cross-sectional distribution of the families' catering incentives, we classify a family as *catering-oriented* (*non-catering-oriented*) in any given year when its *Fam_Num_UIT* or *Fam_Rank_UIT* belongs to the top (bottom) tercile of all the families in the same domicile country. This definition will be used when we examine, for instance, the influence of catering-oriented ownership on price efficiency. It is important to notice that we experiment with different thresholds to define market-oriented families and that the results are robust to these alternative thresholds.

For tests related to market influence, we also define two sets of variables to measure the aggregate active ownership of all catering-oriented families for each stock. More specifically, *CateringForOwnAll_Num* and *CateringForOwnAll_Rank* refer to the aggregate (i.e., the summation of) ownership of all foreign funds offered by catering-oriented families whereby the catering incentive is defined by *Fam_Num_UIT* and *Fam_Rank_UIT*, respectively. Likewise, we use

CateringForOwnNew_Num and *CateringForOwnNew_Rank* to refer to the ownership of new funds created by catering-oriented cross-border expansions during the current year.

C. Variables on Fund Performance

We now describe both our measures of fund/family performance and other characteristics. For a new cross-border expansion, we measure its return, labeled *New Fund Return*, as its average monthly return over the five-year period after the inception, and we define its risk-adjusted performance, labeled *New Fund 4-Factor-adjusted Return*, as the Fama-French-Carhart four-factor-adjusted fund performance over the same period. The risk adjustment is computed as the realized fund returns minus the product between the fund's four-factor betas and the realized four-factor returns in a given month. The four Fama-French-Carhart (FFC, Fama and French, 1993; Carhart, 1997) factors (market, size, book-to-market, and momentum) are measured in the target country in which the new fund aims to invest. The betas of the fund are estimated as the exposures of the fund to the relevant risk factors with a five-year estimation period.

Next, we measure the performance of the affiliated domestic funds of a family, where by "domestic" we mean funds investing in the family's domicile country. We define *Family Domestic Return* as (one-month lagged) TNA-weighted average return of all domestic funds within the same family. We define *Family Domestic 4-Factor-adjusted Return* as TNA-weighted Fama-French-Carhart four-domestic-factor adjusted performance of each fund. The performance of all the affiliated foreign funds of a family, where by "foreign" we mean funds investing in countries that differ from the family's domicile country, is computed in a similar manner (we exclude newly launched foreign funds, whose impact is already captured by *New Fund Return*). That is, we compute *Family Foreign Return* as the fund TNA-weighted return of all foreign funds within the same family and *Family Foreign 4-Factor-adjusted Return* as TNA-weighted four international factors (market, size, book-to-market, and momentum) adjusted return. The performance of the affiliated domestic and foreign funds of a family is measured over the five-year period after the cross-border expansion, and later, we relate the performance to the catering incentives of fund companies.

In robustness checks, we also compute the 8-Factor-adjusted Return for foreign funds (i.e., newly launched foreign funds and existing foreign funds of a fund family), including four domestic Fama-French-Carhart factors and four foreign Fama-French-Carhart factors that are the value-weighted averages of the four domestic factors in all the other countries. Thus, for newly launched foreign funds, we can construct New Fund 8-Factor-adjusted Return; for all foreign funds of a family, we also have Family Foreign 8-Factor-adjusted Return.

Although so far we have focused on the net return delivered to mutual fund investors after all fees and expenses, we also consider gross-of-fee performance. Gross-of-fee fund return is computed as the fund's total return plus one-twelfth of the annualized expense ratio, and gross-of-fee family domestic (foreign) return is computed as (one-month lagged) TNA-weighted gross-of-fee return of all its domestic (foreign) mutual funds. The gross-of-fee returns are further adjusted by a Fama-French-Carhart four-factor model. Our results are robust to these additional performance measures.

D. Control Variables and Other Variables for Fund Family Tests

For fund family tests, we control for four sets of variables that may affect the operations of fund families in general and their overseas operations in particular. The first set is related to family characteristics. These variables include *Log (Family TNA)*, defined as the logarithm of family total net assets (TNA); *Expense Ratio*, defined as the family expense ratio, computed as the fund TNA-weighted annualized expense ratio of all funds within the family; *Family Turnover*, defined as the logarithm of family age, where family age is computed as the fund TNA-weighted number of operational months since inception of all funds within the family; *Family Return*, defined as the fund TNA-weighted return of all funds within the family; *Family Return*, defined as the fund TNA-weighted return of all funds within the family; *All fund TNA values are one-month lagged*.

The second set of variables involves the characteristics of the target country that are important for the operation of foreign funds. These variables include the following: *Log (Distance)*, defined as the logarithm of the geographical distance between the target and the domicile country; *Stock Market Turnover*, defined as the total value of shares traded during the year divided by the average market capitalization; *Stock Market/GDP*, defined as the stock market capitalization divided by nominal GDP; and *Private Bond Market/GDP*, defined as the domestic credit value to private sector divided by nominal GDP. The first variable proxies for the availability of information; the second variable describes the general liquidity conditions in the target market; and the third and fourth variables proxy for the degree of financial development in the target country.

The third set of control variables describes an alternative motivation for fund expansion: international diversification. Fund companies may use cross-border expansion to enhance diversification when their existing products are correlated either with each other or with products offered by other companies. To capture the former effect, we follow Elton, Gruber, and Green (2007) and define a variable measuring the *Within Family Correlation* as *Within Family Corr_{F,t}* = $\frac{1}{N_t}\sum_{i\in F, j\in F} Corr(R_{i,m,t}, R_{j,m,t})$, where $R_{i,m,t}$ and $R_{j,m,t}$ refer to the monthly return of funds *i* and *j* in month *m* of year *t*, both funds are affiliated with family *F*, and N_t refers to the number of fund pairs included in the family. Similarly, we define the *Outside Family Correlation* as *Outside Family Corr_{F,t}* = $\frac{1}{N_t}\sum_{i\in F, j\notin F} Corr(R_{i,m,t}, R_{j,m,t})$, where $R_{i,m,t}$ and $R_{j,m,t}$ refer to the monthly return of funds *i* and *j* in month *m* of year *t*, with fund *i* affiliated with family *F* and fund *j* outside family F but in the same domicile country, and N_t refers to the total number of fund pairs, following Elton, Gruber, and Green (2007).

Note that building on the above intuition, we can also identify the *ex post* diversification benefit that new funds may help investors achieve in two closely related variables. The first variable, *New Fund Correlation Within Family*, is the return correlation or style-adjusted return correlation between the newly launched fund and those of existing affiliated funds managed by the same mutual fund family over the five-year period after its inception. The second, *New Fund Correlation Outside Family*, is defined similarly as the return correlation between a newly launched fund and all the other existing funds outside the mutual fund family but domiciled in the same country. In later sections, we will use these variables to examine whether investors can achieve diversification benefits from catering-oriented cross-border expansions.

The final set of control variables describes the competition conditions of the fund families. In particular, we compute the degree of concentration, HHI_Dom , as the Herfindahl-Hirschman index for all funds domiciled in country *C* in month *m*: $HHI_Dom_{C,m} = \sum_{f \in C} \left(\frac{TNA_{f,m}}{\sum_{f \in C} TNA_{f,m}}\right)^2$, where $TNA_{f,m}$ refers to the total net assets of fund *f* in month *m*, and fund *f* has country *C* as its domicile country. A higher concentration implies a lower degree of competition among funds (using family-level asset concentration does not change our results). We also construct a proxy for the competition in the target country. In addition, we use HHI_Family , defined as the Herfindahl-Hirschman index of the degree of concentration of the family in its funds, to control for the potential competition conditions within a family. Finally, we consider the possibility of launching new funds in the domicile country (instead of in foreign markets) and construct a variable *Num_Index_Dom*, defined as the total number of indices in the domicile country.

E. Variables on Market Influences

Finally, we move on to stock-level variables for tests related to market influences. We first measure three types of market influences that catering-oriented cross-border capital flows can have: price efficiency, liquidity, and market integration. Price efficiency is measured by price delay with respect to global or local market information. For instance, price delay with respect to the global market is defined as follows:

$$Delay_Global_{i,t} = 1 - \frac{R_{restricted,i,t}^2}{R_{unrestricted,i,t}^2},$$
(1)

where $R_{restricted,i,t}^2$ and $R_{unrestricted,i,t}^2$ refer to the R-square from restricted and unrestricted market models estimated using weekly returns in each year *t*. The restricted model (RM) and the unrestricted model (UM) are defined, respectively, as follows:

RM:
$$R_{i,w,t} = \alpha_{i,t} + \delta_{i,0,t} R_{g,w,t} + \sum_{k=0}^{3} \gamma_{i,k,t} R_{l,w-k,t} + e_{i,w,t},$$
 (2A)

UM:
$$R_{i,w,t} = \alpha_{i,t} + \sum_{k=0}^{3} \delta_{i,k,t} R_{g,w-k,t} + \sum_{k=0}^{3} \gamma_{i,k,t} R_{l,w-k,t} + e_{i,w,t},$$
 (2B)

where $R_{i,w,t}$ refers to the accumulated return of stock *i* in week *w* of year *t*, and $R_{g,w-k,t}$ and $R_{l,w-k,t}$ refer to the contemporaneous and lagged returns on the value-weighted world market portfolio and the local market portfolio, following Hou and Moskowitz (2005), and Bae, Ozoguz, Tan, and Wirjanto (2012). Price delay to the domestic market, $Delay_Local_{i,t}$, is defined in a similar manner when the coefficients of the lagged local market returns are set equal to zero in the restricted model (Equation (2A)).

We define illiquidity as the Amihud (2002) illiquidity measure and the proportion of zero daily returns (Lesmond, Ogden, and Trzcinka, 1999). We label them Log(Amihud) and %Zero, respectively. We define the commonality in liquidity for stock *i* in month *m* as follows:

$$\widehat{\omega}_{i,m,d}^{Liq} = \alpha_{i,m}^{Liq} + \sum_{j=-1}^{1} b_{i,m,j}^{Liq} \widehat{\omega}_{M,m,d+j}^{Liq} + \varepsilon_{i,m,d}^{Liq},$$
(3)

where $\omega_{i,m,d}^{Liq}$ is the residual from the following time-series regressions: $Liq_{i,m,d} = \alpha_{i,m}^{Liq}Liq_{i,m,d-1} + \sum_{\tau=1}^{5} \beta_{i,m,\tau}^{Liq} D_{\tau} + \gamma_{i,m}^{Liq} HOLI_{m,d} + \omega_{i,m,d}^{Liq}$, $Liq_{i,m,d}$ is the Amihud liquidity proxy for stock *i* on day *d* of month *m*, defined as $-\log(1 + Illiq_{i,m,d})$, with $Illiq_{i,m,d} = |R_{i,m,d}|/(P_{i,m,d} \times N_{i,m,d})$, $|R_{i,m,d}|$ is the absolute value of return of stock *i* on day *d* of month *m*, $P_{i,m,d}$ is the daily closing price of stock *i*, $N_{i,m,d}$ is the number of shares of stock *i* traded during day *d*, and $HOLI_{t,d}$ is a dummy for trading days around non-weekend holidays. $\widehat{\omega}_{M,m,d+j}^{Liq}$ is the market value (at the end of previous year) weighted average of the residuals for all stocks. The R-square $(R_{i,m}^2)$ from Equation (3) measures the commonality in liquidity for stock *i* of month *m*. We use the logistic transformation of the R-square measures to proxy for liquidity co-movement, i.e., $\ln\left(\frac{R_{i,m}^2}{1-R_{i,m}^2}\right)$, following Karolyi, Lee, and van Dijk (2012).

In line with the international asset pricing literature (e.g., Griffin, 2002; Fama and French, 2012; Hou, Karolyi, and Kho, 2011; Massa and Schumacher, 2015; Karolyi and Wu, 2016), we define market integration as the absolute value of the intercept (i.e., */Intercept/*) and the adjusted R-square of a regression of stock returns on alternative factor models (labeled *Co-movement*). We consider integration with respect to domestic factors (market, size, book-to-market and momentum) and integration with respect to foreign factors (value-weighted four factors excluding the domestic country).

Stock-level control variables include the following: *Log(Stock Size)*, defined as the logarithm of the market value of the stock; *Turnover*, defined as the annual turnover ratio of the stock; *Log(Net Income)*, defined as the logarithm of its net income; *Log(Sales)*, defined as the logarithm of its sales; *Log(Total Assets)*, defined as the logarithm of its total assets; *Stock Return*, defined as the monthly stock return as reported in Datastream/Worldscope; *Domestic IO*, defined as the domestic mutual fund ownership; and *Foreign IO*, defined as the foreign mutual fund ownership. Among the stock variables, we consider alternative measures of market efficiency that we will define in the last section of the paper.

F. Summary Statistics

We now report the summary statistics in Table 1. Panel A reports the mean, median, standard deviation, and the quantile distribution of the number and rank of unexplored indices at the country and family levels, monthly fund and family return, and other annual family and country characteristics. The sample consists of all mutual fund families with the foreign expansion of active equity mutual funds over the 2001 – 2012 period. The summary statistics for the full sample, including index funds, are largely similar because of the popularity of active funds in cross-border expansions, as previously explained (we tabulate the summary statistics for the full sample in Table IA1 in the Internet Appendix). Panel B reports similar statistics for stock-level variables and characteristics.

We see that the catering attractiveness of countries varies drastically in the sample. The number of unexplored indices ranges from zero, when the market is well explored by global investors because all indices are covered by some foreign fund families, to 21 at the 90% quantile, when the market provides plenty of opportunities for foreign investors to explore. Likewise, the catering incentives of global mutual fund families also vary substantially, ranging from zero to 21 at the 90% quantile, suggesting that some families are indeed specialized in catering-oriented cross-border expansions.

Panel C reports the correlation matrix of the main dependent and independent variables. The correlation between price efficiency with respect to global information (*Delay_Global* proxies for lack of price efficiency) and ownership of active catering-oriented funds is negative. Moreover, price efficiency is also negatively correlated with the new ownership created by newly launched active catering-oriented funds. In general, these observations are consistent with the low-skill expansion hypotheses. Of course, it is difficult to conclude from these summary statistics that catering-oriented expansions are associated with low-skilled families. We therefore move on to multivariate regressions to formally establish this key relationship.

III. Catering-Oriented Cross-Border Expansions and Performance

In this section, we first examine the incentives of cross-border expansions. We then investigate the relationship between catering incentives and family skill. Finally, we study investor welfare in terms of diversification benefits.

A. The Decision to Expand to Overseas Markets

We begin by examining the incentives of mutual fund family foreign expansion. To achieve this goal, we first relate the expansion policy of the mutual fund family to the market attractiveness of the specific country and estimate the following annual logistic or probit regression:

$$Expansion_{F,C,t} = \alpha + \beta Num_UIT_{C,t-1} + \gamma M_{F,C,t-1} + e_{F,C,t},$$
(4)

where $Expansion_{F,C,t}$ refers to a dummy variable that equals one if the mutual fund family F begins a new foreign fund in target country C in year t and zero otherwise, while $Num_UIT_{C,t-1}$ refers to the number of indices unexplored by foreign mutual funds in target country C. The vector M stacks all four sets of control variables related to family characteristics (i.e., Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, and Family Flow), target country characteristics (i.e., Log(Distance), Stock Market Turnover, Stock Market/GDP and Private Bond Market/GDP), alternative diversification motivations (i.e., Within Family Correlation and Outside FamilyCorrelation) and competition conditions (i.e., HHI_Dom , HHI_Target , HHI_Family , and Num_Index_Dom). We focus on active fund expansions, include year-fixed effects and cluster the standard errors at the family level.

We report the results in Panel A of Table 2, Models (1) to (4) for logistic specifications and Models (5) to (8) for probit specifications. To see the potential influence of the control variables, we include each set of them in a different model. Hence, Model (1) controls for family characteristics. Model (2) further controls for country characteristics. Models (3) and (4) further include other motivations of overseas expansions and competition conditions. We find that across all specifications, the foreign expansion policy of mutual fund families is positively related to the number of unexplored indices in the target country. The economic effect is also sizable. In Model (4), for instance, an increase of one unexplored index raises the probability of entering a particular country—among all potential foreign countries—by 20%.⁷ This compares to a 4% unconditional probability of entry—i.e., 4% of family-country-year observations will have a new entry. Thus, it is quite common for fund families to pursue catering-oriented overseas expansions.

It is also worth noting that among the control variables, overseas expansion is negatively related to *within family return correlation*. This relation is inconsistent with the idea that diversification is an important motivation for foreign expansion because we should expect families with low existing

⁷ For logistic regression, the economic magnitude is computed as $e^{0.182} - 1 = 0.2$, where 0.182 is the regression coefficient in Model (4).

diversification (i.e., when existing funds are more correlated with each other) to expand more to overseas markets to allow investors to benefit from international diversification. In contrast, overseas expansion is positively related to *Outside Family Correlation*. If we interpret this variable as product similarity (e.g., investors may treat funds of highly correlated returns as close substitutes), then a positive relationship implies a motivation for overseas expansion similar to that for product differentiation. The control of such alternative motivations (along with other characteristics), however, does not affect the influence of our main variable, suggesting that catering incentives are unique in influencing fund families to expand overseas.

Thus far, Panel A demonstrates the existence of catering incentives for global mutual fund companies to initiate their overseas expansions. The next question is what kind of companies are more likely to adopt catering-oriented overseas expansions. Before we move on to formally answer this question, some simple statistics from a portfolio-based analysis will be helpful. At the beginning of each year, we sort mutual fund families into terciles within the domicile country according to their lagged catering incentives (Low, Mid, High), proxied by the average number of unexplored indices of all funds launched by a family in the previous year (Panel B1 for *Fam_Num_UIT* and Panel B2 for *Fam_Rank_UIT*). We then tabulate in Models (1) to (4) of Panel B some of the key characteristics of funds newly launched by families within each tercile, including *Expense Ratio*, *Turnover*, *Log* (*TNA*), and *Return*. For each variable within each tercile, we first compute its average value in a given year across all families in the same domicile country, then take the portfolio average across all countries, and finally report its time-series average value along with its corresponding Newey-West adjusted *t*-statistics. The line "Low-minus-High" tabulates the difference between low catering incentive families in these characteristics.

We first observe that the funds launched by families of high catering incentives are associated with lower turnover ratio and lower returns. Although these features are consistent with the notion that these funds have lower skills to trade and to generate performance, we must further examine the relationship between returns and fees before arriving at any conclusion. If lower returns are associated with higher fees, for instance, then the above features may imply a fee strategy rather than trading skills. However, we find that the Low-minus-High fee difference is positive in Panel B1, suggesting that funds launched by families of *high* catering incentives have *lower* expense ratios (than those associated with low catering incentives). Although the fee difference becomes insignificant in Panel B2 (when catering incentives are proxied by the rank of unexplored indices), its sign remains unchanged. Families with high catering incentives therefore charge lower fees for their new funds. Their poor reported returns in this case signal lower skills as opposed to a fee strategy, consistent with the low-skill expansion hypothesis.

Ex post poor performance, however, does not seem to significantly hurt catering-oriented fund families in raising capital for their new funds. Indeed, the Low-minus-High difference in *Log*

(TNA)—where TNA indicates the amount of capital that these new funds can raise—is largely insignificant, suggesting that style investors who are interested in such new indices cannot predict fund returns. Otherwise, investors should invest more capital in funds that are likely to generate more *ex post* performance—i.e., fund families with low catering incentives. This allocation inefficiency gives rise to the opportunity for low-skilled funds to use catering-oriented overseas expansions to achieve asset growth.

To examine the growth strategies of different fund families, Model (5) presents the overall external asset growth rate (i.e., asset growth that is not attributable to performance) for mutual fund families. We can see that overall asset growth is not significantly different between families with low and high catering incentives. To reconcile this result with fund return, we examine the two mechanisms of external asset growth: the launch of new funds and the attraction of fund flows (by existing funds). More specifically, Models (6) and (7) report a new fund-implied asset growth rate and a flow-implied asset growth rate. Although catering-oriented fund families attract lower fund flows to their existing funds, consistent with their inferior performance, they manage to attract external capital by launching new funds.

Overall, these results suggest that fund families with higher catering incentives are likely to have lower skills and that high-skill and low-skill fund companies have exhibited different growth paths in the era of globalization: the growth of the former (the latter) leans more toward flows (new funds). Since these conjectures have important normative implications, in the next session we will formally examine the relationship between catering incentives and the performance associated with them.

B. Performance of Catering-Oriented Expansions

To better assess the incentives of cross-border expansions, we next investigate the performance of new funds that have been launched for catering purposes. We therefore estimate the following specification:

$$Perf_{f,t:t+4} = \alpha + \beta \times Num_UIT_{f,t-1} + \gamma M_{f,t-1} + e_{f,t},$$
(5)

where $Perf_{f,t:t+4}$ refers to the average monthly return or performance of fund f in five years (year t to t + 4) after inception, and $Num_UIT_{f,t-1}$ refers to the number of unexplored indices in the country where fund f invests (we also use the rank of the unexplored index, $Rank_UIT_{f,t-1}$, as a robustness check). The vector M stacks all other family and country control variables (the four sets of control variables as described before), including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, Log (Distance), Stock Market Turnover, Stock Market/GDP, Private Bond Market/GDP, Within Family Correlation, Outside Family Correlation, HHI_Dom, HHI_Target, HHI_Family, and Num_Index_Dom. If a fund f has been launched to invest in a target country with more unexplored indices, its higher value of $Num_UIT_{f,t-1}$ reveals a more pronounced

catering purpose of the fund inception than, at least, the case in which the fund invests in a country with fewer unexplored indices.

We report the results in Table 3. Models (1) and (2) tabulate the results for the returns of new funds, whereas Models (3) and (4) report those for four-factor-adjusted fund performance. We find that the new funds launched for catering purposes perform poorly in the subsequent five years after inception. This finding holds across all the specifications and is not only statistically significant but also economically relevant. Indeed, a one-standard-deviation increase in the number (rank) of unexplored indices reduces annual returns and risk-adjusted performance by 0.31% and 1.43% (0.33% and 0.97%).⁸

As a robustness check, we also apply the same test to the sample of all foreign expansions (including index funds) and the smaller sample of active foreign expansions (excluding all closetindex funds) (i.e., Cremers, Ferreira, Matos, and Starks, 2016) from the sample of active funds. These two tests alleviate the potential concern that our results can be contaminated by index funds or closetindex funds (footnote 5 provides a more detailed discussion of this point). In addition, we consider alternative performance measures such as 8-factor adjusted return including four FFC domestic, four FFC foreign factors, and gross-of-fee performance. In the interest of brevity, we report the results in the Internet Appendix (Table IA2; Panel A for all foreign expansions, Panel B for active funds excluding all closet indexers, Panel C for 8-factor adjusted return, and Panel D for gross-of-fee performance). We can see that poor performance is associated with new funds' catering incentives in all the samples of funds we have examined and across all performance measures.

C. Performance of Catering-Oriented Families

The above results deliver the message that the decision to offer new funds has a major catering-driven component associated with lower performance. This observation leads to a more general question: is it true that low-skilled families concentrate on catering incentives due to their inability to deliver performance? To answer this question, we use family performance in the domestic market as a measure of skill because mutual funds are arguably better at processing domestic information, and we relate skill to families' catering incentives. More specifically, we estimate the following specification:

$$DomPerf_{F,t:t+4} = \alpha + \beta \times CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t}, \tag{6}$$

where $DomPerf_{F,t:t+4}$ refers to the performance of the existing domestic portfolios of fund family *F* in five years (year *t* to *t* + 4) after its foreign expansion (i.e., *Family Domestic Return* or *Family*

⁸ The economic magnitude of the performance regression of $y = \beta \times x$ is computed as $\beta \times \sigma_x$, where y and x are the dependent and independent variables, respectively, β is the regression coefficient, and σ_x is the standard deviation of x. For instance, the standard deviation of horizontal $Rank_UIT_{f,t-1}$ is 0.289, and the regression coefficient in Model (2) is -0.094. Since the dependent variable is monthly percentage return, we compute the annualized economic magnitude as $-0.094\% \times 0.289 \times 12 = -0.33\%$.

Domestic 4-Factor-adjusted Return as defined above), and *CateringIncentive*_{F,t-1} refers to the two measures of a family's catering incentives (i.e., *Fam_Num_UIT* or *Fam_Rank_UIT*). The vector M stacks all other family and domicile country control variables, including *Log(Family TNA)*, *Expense Ratio, Family Turnover, Log(Family Age), Family Return, Within Family Correlation, Outside Family Correlation, HHI_Family*, and *Num_Index_Dom*.

We report the results in Table 4 for all families that have launched active funds in another country. Models (1) and (2) tabulate the results for the returns of the existing domestic funds, whereas Models (3) and (4) report the results for four-factor-adjusted fund performance. The results show that fund families' catering incentives are typically associated with underperformance in the domestic market. A one-standard-deviation increase in fund companies' catering incentive in terms of the average number (rank) of unexplored indices reduces returns and risk-adjusted performance by 0.36% and 0.21% (0.33% and 0.21%). As a result, we can conclude that catering-oriented families are of low skills to explore investing opportunities in their own domestic market.

As a further robustness check, we also apply the test to 1) the sample including families that launch only foreign index funds, and 2) the sample excluding families that launch only foreign closetindex funds. To save space, we tabulate the results in Panels A and B of Table IA3 in the Internet Appendix. Our results remain unchanged, confirming that index funds and closet-index funds are not a concern for our results.

Another related concern is that some families may charge consistently higher fees than others, leading to their funds' lower after-fee performance. Panel C of Table IA3 provides additional robustness checks using gross-of-fee performance of mutual fund families. Our results are again robust, suggesting that fee strategy is not a major driving force for our performance results. This conclusion is consistent with those of previous univariate tests (Table 2 Panel B).

To further gauge the economic impact of catering incentives, we perform a portfolio-based analysis and report the results in Table 5. We proceed as follows. At the beginning of each year, mutual fund families are sorted into terciles within the domicile country according to their lagged catering incentives, proxied by the number and the rank of unexplored index at the family level ($Fam_Num_UIT_{F,t-1}$ and $Fam_Rank_UIT_{F,t-1}$). We then construct portfolios going long (short) the Low (High) catering incentive families and calculate their holding period (year *t*) monthly returns. The returns are first averaged across fund families within the same domicile country and then averaged across countries. Next, we calculate performance of these portfolios by using either a onefactor model (international market factor) or a Fama-French-Carhart four-international-factor model comprising the market, size, book-to-market, and momentum factors. The "LMH" rows report the difference in profits between low and high catering incentive portfolios. We adjust the errors using a Newey-West adjustment. We find that in line with the previous findings, the families with high catering incentives underperform those with low catering incentives by 2.78% (2.77%) per year in FFC four-factor alpha when catering incentives are proxied by the number (rank) of unexplored indices.

As an important subsample test, we also examine the foreign expansion of U.S. mutual fund families. We report the results in Table 6. Models (1) to (2) re-estimate Equation (4), and Models (3) to (4) re-estimate Equation (6). We find that our main results hold for U.S. mutual fund families. An increase of one number of unexplored indices increases the probability of expansion by 41%, and a one-standard-deviation increase in fund companies' catering incentive in terms of the average number (rank) of unexplored indices reduces risk-adjusted performance by 0.34% (0.2%) per year.

Finally, we examine the performance of foreign funds. We ask whether there is a link between the decision of the family to expand for catering reasons and its ability to perform abroad. We therefore re-estimate the same specifications as Equation (6), while using as a dependent variable the performance of the family abroad. We consider both a multivariate analysis and a portfolio-based one, as in the previous case of domestic performance. In particular, we estimate the following:

$$For Perf_{F,t:t+4} = \alpha + \beta \times CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t},$$
(7)

where $ForPerf_{F,t:t+4}$ refers to the average monthly return of the existing foreign portfolios of fund family *F* in five years (year *t* to *t* + 4) after its foreign expansion (i.e., *Family Foreign Return* or *Family Foreign 4-Factor-adjusted Return* as defined above), and *CateringIncentive*_{F,t-1} is our measure of catering incentives of fund families as before. The vector *M* stacks all other family and country control variables, as defined in Table 4.

We report the results in Table 7. In Panel A, we report the results based on multivariate analysis, and in Panel B, we report the results of the portfolio-based analysis. We find that families that expand for catering reasons underperform in the foreign market. This result holds both in the multivariate analysis and in the portfolio-based analysis. This underperformance is strongly economically and statistically significant. For instance, a one-standard-deviation increase in fund companies' catering incentive in terms of the average number (rank) of unexplored indices reduces returns and risk-adjusted performance by 0.21% and 0.21% (0.19% and 0.14%). In addition, families with high catering incentive underperform those with low catering incentive in their foreign funds by 2.09% to 2.56% per year (in FFC four-factor alpha).

Similar to the case of domestic fund performance, we examine the relationship between the performance of a family's foreign funds and its catering incentive for 1) all the families that have foreign expansion (i.e., to further include families that launch only foreign index funds) and 2) the families that have active foreign expansions excluding closet indexers (i.e., to further exclude families that launch only foreign closet-index funds). The results are also tabulated in Panels A and B of Table IA3 in the Internet Appendix. The only difference with respect to the tests based on domestic funds is

that we further adjust the performance of the foreign funds using an 8-factor model that includes both domestic and foreign factors. Panel C of Table IA3 provides additional robustness checks using the gross-of-fee performance of foreign funds. Our main conclusion remains unchanged across all these different specifications.

From these tests, we find that in general, higher catering incentives are related to low performance for all the categories of funds that a family offers. As a final step to understand the wealth implications for investors, we investigate whether catering-oriented funds can enhance diversification benefits.

D. Investor Welfare in terms of Diversification Benefits and Hedging Against Crisis

Although our performance tests strongly suggest that catering-driven investment is likely to be conducted by low-skilled fund families, a residual issue is whether catering-driven investment is more closely related to portfolio diversification than to performance. If so, low performance does not necessarily indicate low investor welfare. Instead, low performance can be compensated by a higher degree of international diversification. For instance, these cross-border expansions may reduce the average correlation across funds offered by a same family, thereby allowing family investors to enjoy more diversification benefits. To formally investigate this issue, we relate the *ex post* diversification benefit of the new funds to our catering proxy as follows:

$$Diversification_{f,t:t+4} = \alpha + \beta Num_UIT_{f,t-1} + \gamma M_{f,t-1} + e_{f,t},$$
(8)

where $Diversification_{f,t:t+4}$ refers to the diversification proxy of fund f in five years (year t to t + 4) after inception, and $Num_UIT_{f,t-1}$ measures the catering incentives of fund f as before (we also use $Rank_UIT_{f,t-1}$, as a robustness check). The vector M stacks all other family and country control variables, including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, Log (Distance), Stock Market Turnover, Stock Market/GDP, Private Bond Market/GDP, Within Family Correlation, Outside Family Correlation, HHI_Dom, HHI_Target, HHI_Family, and Num_Index_Dom.

We report the results in Table 8. In Models (1) to (2) and Models (3) to (4), we measure the (lack of) diversification benefit by return correlation and style-adjusted return correlation between the newly launched fund and other funds within the same family, respectively. In Models (5) to (6), we examine the return correlation between the newly launched fund and other funds outside the family but within the same domicile country. We focus on the newly launched active funds and find that expansions oriented from catering purposes do not gain diversification benefits. In contrast, a one-standard-deviation increase in fund companies' catering incentive in terms of the average number (rank) of unexplored indices increases the correlation of the new fund with the family by 1.35% and 2.05% (1.29% and 1.48%) in the case of fund performance and style-adjusted performance.

Next, we explore whether overseas expansions can benefit investors by offering a hedge against crisis—i.e., to deliver performance during a crisis period. Models (7) to (8) investigate the risk-adjusted performance of newly launched funds during the 2008-2009 financial crisis. We can see that these funds do not deliver performance during crisis. Unreported tests show that when we interact a crisis period dummy with catering incentives, the interaction is also insignificant. These findings do not support the view that catering-oriented funds are launched as an instrument to hedge crisis.

Overall, these results suggest that higher catering incentives are related to low performance that is not compensated for by the benefits of higher diversification. Thus, the data support the prediction of the catering-oriented low-skill expansion hypothesis in that catering-oriented overseas expansions are likely to be a competition tool used by low-skilled fund companies. The next step is to investigate whether such low-skilled, catering-oriented cross-border capital flows affect the stock market.

IV. Influences of Catering-Oriented Cross-Border Capital Flows

We now investigate the link between catering-driven expansion and market efficiency. We focus mainly on three dimensions that could best demonstrate the (different) market influence of cross-border capital flows: informational efficiency, liquidity, and market integration. These three dimensions of influences will allow us to understand the difference between catering-oriented cross-border capital flows and the general cross-border capital flows that are typically examined in the literature.

A. On Price Efficiency

We begin with the important finding of Bae, Ozoguz, Tan, and Wirjanto (2012) that foreign capital can improve the informational efficiency in emerging markets by better processing global information, and we examine whether catering-oriented capital flows are associated with similar benefits. To achieve this goal, we examine the relation between price delay to global market information, the main variable of informational efficiency in Bae, Ozoguz, Tan, and Wirjanto (2012), and the ownership of actively managed foreign funds offered by catering-oriented fund families. We estimate the following panel specification with year and stock fixed effects and standard errors clustered at the stock level:

$$Delay_{i,t} = \alpha + \beta \times CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t},$$
(9)

where $Delay_{i,t}$ refers to the price delay of stock *i* in year *t* to the global market information $(Delay_Global_{i,t})$ or the local market information $(Delay_Local_{i,t})$, and $CateringForOwn_{i,t-1}$ is the ownership of catering-oriented active foreign funds either by all foreign funds of catering-oriented families ($CateringForOwnAll_{i,t-1}$) or by newly launched catering-oriented funds ($CateringForOwnNew_{i,t-1}$).

Mutual fund families are sorted into terciles within the domicile country according to their lagged catering incentives and proxied by the number and the rank of unexplored index at the family level (*Fam_Num_UIT* and *Fam_Rank_UIT*). Those in the top tercile are defined as catering-oriented families, and the aggregate ownership from their existing (newly launched) affiliated foreign funds is labeled *CateringForOwnAll (CateringForOwnNew)* accordingly. Furthermore, *CateringForOwnAll* (*CateringForOwnNew*) refers to a set of variables—i.e., *CateringForOwnAll_Num* and *CateringForOwnAll_Rank (CateringForOwnNew_Num* and *CateringForOwnNew_Rank)*—when mutual fund families' catering incentives are proxied by *Fam_Num_UIT* and *Fam_Rank_UIT*. Vector *M* stacks all other stock and country control variables, including *Domestic IO*, *Foreign IO*, *Stock Return*, *Log(Stock Size)*, *Turnover*, *Log(Net Income)*, *Log(Sales)*, *Log(Total Assets)*, *Stock Market Turnover*, *Stock Market/GDP*, and *Private Bond Market/GDP*. We include year- and stock fixed effects and cluster the standard errors at the stock level.

We report the results in Table 9, with Models (1) to (6) focusing on delay in processing global information and Models (7) to (12) focusing on delay in processing local information. We find that the capital flows associated with catering-oriented cross-border expansions do not improve the price discovery and overall market efficiency in the target country. In contrast, a one-standard-deviation increase in the ownership of catering-oriented foreign funds identified based on the number (rank) of unexplored indices is related to 1.1% (1.13%) greater price delay (i.e., the influence of additional price delay scaled by the standard deviation of price delay) to the global market information in Model (1) (Model (4)). In addition, and perhaps not surprisingly, high ownership of catering-oriented foreign funds is associated with a more prominent price delay related to domestic market information.

Furthermore, price delay to global market information is typically enhanced after new cateringoriented cross-border expansions. A one-standard-deviation increase in the *new* ownership introduced by catering-oriented cross-border expansions is related to a 1.06% (1.18%) greater price delay in Model (2) (Model (5)). Given that *CateringForOwnNew*_{*i*,*t*-1} is equivalent to changes in cateringoriented ownership introduced by new catering-oriented cross-border expansions, this result directly quantifies the incremental price delay that is likely to be introduced by the new ownership of cateringoriented overseas expansions.

We then examine the influence of fire sale flows of catering-oriented funds in Models (3) and (6). Following Coval and Stafford (2007), fire sale flows of each stock are defined as the net flows of fire purchases of all catering-oriented funds and fire sales of catering-oriented funds, denoted *CateringForOwnFS_Num* and *CateringForOwnFS_Rank*, when mutual fund families' catering incentives are proxied by *Fam_Num_UIT* and *Fam_Rank_UIT*. Appendix A provides more detail on how we construct this variable. Models (3) and (6) show that fire sale flows of catering-oriented funds positively affect price delay. This positive coefficient confirms that price delay increases (decreases) when the ownership of catering-oriented funds increases (decreases) after fire purchases (fire sales).

It is especially striking to see that the influence of catering-oriented foreign capital flows in processing global information is exactly the opposite of that of general foreign capital flows, as reported in the literature (e.g., Bae, Ozoguz, Tan, and Wirjanto, 2012). To reconcile our finding with the literature, we conduct additional tests (reported in Table IA4 in the Internet Appendix) and find that the impact of active cross-border capital flows that are the least related to catering incentives (non-catering funds or associated capital flows) is largely beneficial in processing global information. A one-standard-deviation increase in the ownership of catering-oriented foreign funds (non-catering funds) is associated with a 1.33% greater (0.84% less) price delay with respect to global market information for all countries and a 3.63% greater (2.37% less) price delay for emerging markets. In this regard, catering-oriented foreign capital flows can reduce price efficiency by approximately 6% compared to non-catering-oriented foreign capital flows.

Interestingly, fire sale flows of the least catering-oriented funds are no longer beneficial; they become largely statistically insignificant, suggesting that even funds with the proper incentives may not benefit the investing country when these funds are under the pressure of fire sales (purchases). By contrast, the influence of fire sale flows of catering-oriented funds remains highly significant, suggesting that our test has the proper statistical power to identify the true economic influences of fire sale flows.

The above tests imply a plausibly causal influence of catering-oriented foreign capital flows on price efficiency for several reasons. First, since stock fixed effects are explicitly controlled for in these tests, time-invariant stock characteristics, including those related to price inefficiency, are unlikely to be the driving force of our results. Consider, for instance, the relationship between CateringForOwnNew_{i,t-1} (i.e., ownership introduced by new funds) and subsequent price delay. This positive relationship on itself can arise when newly created catering-oriented ownership reduces price efficiency (which implies a causal influence of the former on the latter) or the reverse (in which case stocks with persistent, high market delay attract new catering-oriented funds). With stock fixed effects, however, the reverse causality is less plausible because persistent stock characteristics should be absorbed. Second, catering- and non-catering-oriented foreign funds have exactly the opposite influences on price delay, suggesting that our findings are not driven by spurious correlations between foreign ownership and price efficiency. Finally, fire sales and purchases are largely exogenous to fund managers (Coval and Stafford, 2007; Jotikasthira, Lundblad, and Ramadorai, 2012). Since there is no reason to believe that fire sales (purchases) can directly influence the price efficiency of another country (except through the investment behavior of these funds (e.g., Jotikasthira, Lundblad, and Ramadorai, 2012), this result based on fire sale flows further alleviates potential endogeneity concerns. Overall, our results capture the influences of time-varying catering incentives of fund ownership, which are difficult to explain through reverse causality or spurious correlation unrelated to the latter.

In addition to price delay, we examine whether these funds are better able to affect price informativeness by processing industry-level information. To test this channel, we construct two measures of delays in processing global industry information and local industry information by replacing the returns of the value-weighted market portfolio with the returns of the value-weighted industry portfolio for the leading industry invested by a fund. Unreported results show that cateringoriented foreign capital flows are unrelated to both delay measures, whereas non-catering-oriented foreign capital flows help process the industry-level information in both the global and the domestic markets. Therefore, catering-oriented foreign capital flows are no better at processing industry-level information than local funds.

These results have important normative implications. They suggest that capital flows are heterogeneous in nature and that there is a significant difference between the impact of "bad" (catering-oriented) capital flows and that of "good" (non-catering-oriented) ones. Hence, a one-policy-for-all regulation may not achieve the intended benefit of the globalization of finance. However, above all, our results suggest that the non-beneficial impact actually comes from catering-oriented and low-skilled foreign expansions.

B. On Liquidity and Commonality in Liquidity

Next, we examine the notion that low-skilled fund companies may supply liquidity to the local market instead of processing information. If so, capital flows associated with these companies are still arguably beneficial to the local economy.

To achieve this goal, we replace price delay in Equation (9) by stock liquidity—proxied by either Amihud's (2002) illiquidity or the proportion of zero daily returns (Lesmond, Ogden, and Trzcinka, 1999)—and commonality in liquidity (Karolyi, Lee, and van Dijk, 2012). We tabulate the results in Table 10. We find that catering-oriented foreign capital flows do not improve liquidity conditions, either. In contrast, a one-standard-deviation increase in the ownership of (rank-based) catering-oriented foreign funds is associated with an increase in Amihud *illiquidity* of 0.29% and an increase of the proportion of zero return days of 1.27% (scaled by the standard deviation of illiquidity measures). Similarly, a one-standard-deviation increase in the new ownership of catering-oriented foreign funds is also associated with an increase in Amihud *illiquidity* of 0.39% and an increase in the proportion of zero return days of 1.25%.

To better understand this result, we revisit the turnover ratio of various types of funds as a proxy for their willingness to trade. We have already seen in Table 2 that catering-oriented foreign funds trade considerably less than non-catering-oriented foreign funds. We further verify in our data that the turnover ratio of catering-oriented foreign funds is 54% less than domestic funds, implying a significant reduction in liquidity. It is not surprising to see that catering-oriented foreign funds have

less willingness to trade. On the one hand, mutual funds usually trade more to exploit profitable investment opportunities (Pástor, Stambaugh, and Taylor, 2017). Since catering-oriented foreign funds are low-skill, they trade less than more informed funds. On the other hand, if these funds' primary goal is to attract capital flows, their trading incentives will be even lower after this catering goal is achieved. These considerations help explain the above results on market liquidity.⁹

Finally, we document that catering-driven flows are also associated with higher commonality in liquidity. A one-standard-deviation increase in ownership of all and new (rank-based) catering-oriented foreign funds is associated with increases in commonality in liquidity with respect to the local market of 1.04% and 0.93%, respectively. This result is also consistent with the finding of Karolyi, Lee, and van Dijk (2012) that the behavior of foreign investors can explain the variations in commonality in liquidity. Although this magnitude is not very large, the message is clear that catering-oriented foreign capital flows do not benefit the local market in terms of liquidity.

Overall, catering-oriented foreign capital flows not only harm the general liquidity condition but also increase commonality in liquidity. While the first influence is unambiguously costly, the latter may also enhance contagion risk by boosting the local economy's commonality in liquidity. Interestingly, the cross-border flows that are least catering-oriented do not improve liquidity conditions either, as Table IA5 in the Internet Appendix indicates. Indeed, they also seem to absorb liquidity, although the results are less robust across different specifications. Given that this type of (least-market-oriented) capital flows process global information, it is not surprising that they may occasionally require liquidation from the local market.

C. On Market Integration

Finally, we consider market integration. Similar to our tests on price efficiency, we separately examine the two cases of market integration: integration with the global market and that with the local market. Recall that market integration is defined as the absolute value of the intercept and the adjusted R-square of a regression of stock returns on global or domestic factor models. As the absolute value of the intercept decreases and the adjusted R-square increases, the degree of integration increases.

We then again conduct a regression specification similar to that in Equation (9), replacing price delay with various measures of market integration. The results are tabulated in Table 11. We find that catering-oriented foreign ownership is not related to integration with respect to overall international market factors.

Jointly, the tests in this section fail to depict a beneficial role of catering-oriented cross-border capital flows. Indeed, these capital flows hurt price efficiency—with respect to both global

⁹ Note that fire sales (purchases) are likely to mechanically dry up liquidity because funds must sell and buy a relatively large number of shares in the market. Our empirical results confirm this intuition. Since the effect is mechanical, we do not tabulate the results here.

information and local information—as well as liquidity conditions. Table IA6 in the Internet Appendix further shows that these results remain valid when we focus only on a subsample of active funds by further excluding closet indexers. In general, these pricing influences are consistent with the previous section's results that such capital flows are likely to be managed by low-skilled families.

Conclusion

In this paper, we study how financial globalization may unintendedly reduce market efficiency through low-skilled mutual fund companies. The globalization of finance, despite all its beneficial influences, may allow low-skilled mutual fund companies to achieve product differentiation by launching new funds for catering purposes rather than for the improvement of investor welfare or market efficiency. Cross-border capital flows channeled to foreign markets through low-skilled fund companies for catering purposes are unlikely to deliver the benefits of financial liberalization, as documented in the literature. Instead, more capital flows of this type may hurt informational efficiency and the liquidity condition.

Using the complete sample of global mutual funds, we indeed find that catering-oriented fund companies are more likely to launch new funds in foreign markets that have more indices unexplored by the global mutual fund industry. In general, new funds launched this way are associated with lower performance—as are their affiliated funds managed by the same fund company. These findings suggest that low-skilled fund companies can use unexplored foreign indices to differentiate their products. Empirically, cross-border capital flows managed by catering-oriented fund companies increase the degree of market integration with respect to global factors and reduce the price efficiency, even with respect to global information and the general liquidity conditions of a market.

Our key message is that not all flows are the same, depending on who manages them, which highlights the importance of heterogeneity among cross-border capital flows. Our findings have important normative implications for regulations and call for more research to understand foreign capital flows based on more solid micro-foundations.

Appendix A: Variable Definitions

| Variables | Definitions |
|--|--|
| A. Catering Incentive Measures (in %) Num_UIT | The number of unexplored indices in the target country refers to the total number of indices in that country tracked by domestic funds that are not yet invested in by any foreign funds. It is computed as the total number of indices tracked by mutual funds minus the number of indices invested by foreign funds in the country where a new fund is launched. The index tracked by mutual funds in each country first comes from Morningstar 'Primary Prospectus Benchmark ID', and the name 'Primary Prospectus Benchmark' is used if 'Primary Prospectus Benchmark ID' is missing. For each index, a domicile country is assigned based on the market in which the majority of the stocks included in the index are traded, and a foreign fund to an index is defined as a fund whose domicile country is different from that of the index. |
| Rank_UIT | Rank the number of unexplored indices (<i>Num_UIT</i>) in the target country across all newly launched funds from the same domicile country, and the ranks are normalized to follow a [0, 1] uniform distribution. |
| Fam_Num_UIT | The number of unexplored indices at the family level is computed as the average number of unexplored indices in the target country across all newly launched funds within the same family. The rank of unexplored indices at the family level is computed as the average rank of unexplored |
| Fani_Kank_011 | indices in the target country across all newly launched funds within the same family. |
| CateringForOwnAll_Num (in %) | The aggregate ownership of all existing foreign funds offered by catering-oriented families, when catering-oriented families are defined as those with <i>Fam_Num_UIT</i> , belongs to the top tercile among all families in the same domicile country. The catering-oriented foreign ownership is computed as the total number of shares held by mutual funds affiliated with catering-oriented families divided by the number of shares outstanding. |
| CateringForOwnNew_Num (in %) | The aggregate ownership of all newly launched foreign funds offered by catering-oriented families, when catering-oriented families are defined as those with <i>Fam_Num_UIT</i> , belongs to the top tercile among all families in the same domicile country. The variable is defined in a similar manner as <i>CateringForOwnAll_Num</i> . |
| CateringForOwnFS_Num (in %) | The extreme flow-motivated change in ownership of all foreign funds offered by catering-oriented families for stock <i>i</i> in a quarter <i>q</i> is computed as follows: $MktingForOwnFS_Num_{i,q} = \sum_{f} \left(\max(0, \Delta IO_{f,i,q}) flow_{f,q} > PCT90_{q} \right) - \sum_{f} \left(\max(0, -\Delta IO_{f,i,q}) flow_{f,q} < PCT10_{q} \right)$, where $\Delta IO_{f,i,q}$ refers to the change in catering-oriented foreign ownership of stock <i>i</i> held by fund <i>f</i> in quarter <i>q</i> (defined as in <i>CateringForOwnAll_Num</i>), $flow_{f,q}$ refers to the fund flow in the same quarter, $PCT90_{q}$ and $PCT10_{q}$ refer to the 90 th and 10 th percentile of flow across all funds in quarter <i>q</i> , following Coval and Stafford (2007). Fund flow in a given month <i>m</i> is computed as follows: $Flow_{f,m} = [TNA_{f,m} - TNA_{f,m-1} \times (1 + r_{f,m})]/TNA_{f,m-1}$, where $TNA_{f,m}$ refers to the total net asset of fund <i>f</i> in month <i>m</i> , and $r_{f,m}$ refers to fund total return in the same month. Quarterly flow is computed as the sum of monthly flows over the quarter. |
| CateringForOwnAll_Rank (in %) | The aggregate ownership of all existing foreign funds offered by catering-oriented families, when catering-oriented families are defined as those with <i>Fam_Rank_UIT</i> , belongs to the top tercile among all families in the same domicile country. The variable is defined in a similar manner as <i>CateringForOwnAll_Num</i> . |
| CateringForOwnNew_Rank (in %) | The aggregate ownership of all newly launched foreign funds offered by catering-oriented families, when catering-oriented families are defined as those in which <i>Fam_Rank_UIT</i> belongs to the top tercile among all families in the same domicile country. The variable is defined in a similar manner as <i>CateringForOwnAll_Num</i> . |
| CateringForOwnFS_Rank (in %) | The extreme flow-motivated change in ownership of all foreign funds offered by catering-oriented families for stock <i>i</i> in a quarter <i>q</i> is computed as follows: $MktingForOwnFS_Rank_{i,q} = \sum_{f} \left(\max(0, \Delta IO_{f,i,q}) flow_{f,q} > PCT90_{q} \right) - \sum_{f} \left(\max(0, -\Delta IO_{f,i,q}) flow_{f,q} < PCT10_{q} \right)$, where $\Delta IO_{f,i,q}$ refers to the change in catering-oriented foreign ownership of stock <i>i</i> held by fund <i>f</i> in quarter <i>q</i> (defined as in <i>CateringForOwnAll_Rank</i>), and all other variables are defined as in <i>CateringForOwnFS_Num</i> . |
| B. Performance Measures (in %) New Fund Return | Monthly total returns for the newly launched fund, as reported by Morningstar. When a portfolio has multiple share classes, its total return is computed as the share class total net asset (TNA)-weighted return of all share classes, where the TNA values are one-month lagged. |
| New Fund 4-Factor-adjusted Return | Realized fund returns minus the productions between a fund's four-factor betas multiplied by the realized four factor returns in a given month. The four Fama-French-Carhart (FFC) factors (market, size, book-to-market, and momentum) are measured in the target country in which the new fund is launched. The betas of the fund are estimated as the exposures of the fund to the relevant risk factors |

with a five-year estimation period.

| New Fund 8-Factor-adjusted Return | Realized fund returns minus the productions between a fund's eight-factor betas multiplied by the realized eight factor returns in a given month. The eight factors consist of four Fama-French-Carhart (FFC) factors (market, size, book-to-market, and momentum) that are measured in the target country where the new fund is launched, as well as four foreign factors that are the value weighted average of the four factors in all other countries. The betas of the fund are estimated as the exposures of the fund to the relevant risk factors with a five-year estimation period. |
|---|---|
| Family Domestic Return | Family domestic return is computed as the fund TNA-weighted return of all domestic funds within the same family, where the TNA values are one-month lagged, and the domestic fund is defined as a fund tracking an index in the same domicile country. |
| Family Domestic 4-Factor-adjusted | Realized family domestic returns minus the productions between a family's four-factor betas multiplied by the realized four factor returns in a given month. The Fama-French-Carhart factors (market, size, book-to-market, and momentum) are measured in the family's domicile country. The betas of the fund are estimated as the exposures of the fund to the relevant risk factors with a five-year estimation period. |
| Family Foreign Return | Family foreign return is computed as the fund TNA-weighted return of all foreign funds within the same family, where the TNA values are one-month lagged, and the foreign fund is defined as a fund tracking an index outside its domicile country. |
| Family Foreign 4-Factor-adjusted Return | Realized family foreign returns minus the productions between a family's four-factor betas multiplied by the realized four factor returns in a given month. The four international factors are the value weighted average of four domestic Fama-French-Carhart factors (market, size, book-to-market, and momentum). The betas of the fund are estimated as the exposures of the fund to the relevant risk factors with a five-year estimation period. |
| Family Foreign 8-Factor-adjusted Return | Realized family foreign returns minus the productions between a family's eight-factor betas multiplied by the realized eight factor returns in a given month. The eight factors consist of four domestic Fama-French-Carhart (FFC) factors (market, size, book-to-market, and momentum), as well as four foreign factors that are the value weighted average of four domestic factors in all other countries. The betas of the fund are estimated as the exposures of the fund to the relevant risk factors with a five-year estimation period. |
| C. Diversification Measures Within-Family Correlation | Within-family correlation for mutual fund family <i>F</i> in year <i>t</i> is computed as follows: <i>Within Family Corr</i> _{<i>F</i>,<i>t</i>} = $\frac{1}{N_t} \sum_{i \in F, j \in F} Corr(R_{i,m,t}, R_{j,m,t})$, where $R_{i,m,t}$ and $R_{j,m,t}$ refer to the monthly return of fund <i>i</i> and <i>j</i> in month <i>m</i> of year <i>t</i> , with both funds affiliated with family <i>F</i> , and N_t refers to the number of fund pairs included in the family, following Elton, Gruber, and Green (2007). |
| Outside Family Correlation | Outside family correlation for mutual fund family <i>F</i> in year <i>t</i> is computed as follows: <i>Outside Family Corr</i> _{<i>F</i>,<i>t</i>} = $\frac{1}{N_t} \sum_{i \in F, j \notin F} Corr(R_{i,m,t}, R_{j,m,t})$, where $R_{i,m,t}$ and $R_{j,m,t}$ refer to the monthly return of fund <i>i</i> and <i>j</i> in month <i>m</i> of year <i>t</i> , with fund <i>i</i> affiliated with family <i>F</i> and fund <i>j</i> outside family <i>F</i> but in the same domicile country, and N_t refers to the total number of fund pairs, following Elton, Gruber, and Green (2007). |
| New Fund Correlation Within Family | New fund correlation within the family is computed as the return correlation between a newly launched fund and all other existing funds affiliated with the same mutual fund family, defined as the within-family correlation above. |
| New Fund Correlation Outside Family | New fund correlation outside the family is computed as the return correlation between a newly launched fund and all other existing funds outside the mutual fund family but in the same domicile country, defined as the outside family correlation above. |
| D. Market Delay Measures | |
| Delay_Global | The price delay to the global market information for stock <i>i</i> in year <i>t</i> is computed as follows: R^2 |
| | $Delay_Global_{i,t} = 1 - \frac{r_{Pestructed,i,t}}{R_{unrestricted,i,t}^2}$, where $R_{restricted,i,t}^2$ and $R_{unrestricted,i,t}^2$ refer to the R-square |
| | from restricted and unrestricted market models estimated using weekly returns in each year t. Restricted model: $R_{i,w,t} = \alpha_{i,t} + \delta_{i,0,t}R_{g,w,t} + \sum_{k=0}^{3} \gamma_{i,k,t}R_{l,w-k,t} + e_{i,w,t}$; Unrestricted model: $R_{i,w,t} = \alpha_{i,t} + \sum_{k=0}^{3} \delta_{i,t} R_{g,w,t} + \sum_{k=0}^{3} \gamma_{i,t,t}R_{l,w-k,t} + e_{i,w,t}$; |
| | refers to the accumulated return of stock <i>i</i> in week <i>w</i> of year <i>t</i> , and $R_{g,w-k,t}$ and $R_{l,w-k,t}$ refer to the contemporaneous and lagged returns on the value-weighted world market portfolio and the local market portfolio, following Hou and Moskowitz (2005), and Bae, Ozoguz, Tan, and Wirjanto (2012). |
| Delay_Local | The price delay to the local market information for stock i in year t is computed as follows: |
| | $Delay_Local_{i,t} = 1 - \frac{R_{restricted,i,t}^2}{R_{unrestricted,i,t}^2}$, where $R_{restricted,i,t}^2$ and $R_{unrestricted,i,t}^2$ refer to the R-square |
| | from restricted and unrestricted market models estimated using weekly returns in each year t. Restricted model: $R_{i,u,t} = \alpha_{i,t} + \sum_{k=0}^{3} \delta_{i,k,k} R_{i,u,k} + \gamma_{i,k} R_{i,u,k} + \rho_{i,u,k}$ |
| | Unrestricted model: $R_{i,w,t} = \alpha_{i,t} + \sum_{k=0}^{3} \delta_{i,k,t} R_{g,w-k,t} + \gamma_{i,0,t} R_{i,w,t} + e_{i,w,t}$, where all variables are defined as in $D_{i,k,t} Classical defined as in D_{i,k,t} R_{i,k,t} R_{i,k,t} R_{j,w-k,t} + \sum_{k=0}^{3} \gamma_{i,k,t} R_{i,w-k,t} + e_{i,w,t}, where all$ |
| | variables are defined as in <i>Delay_Global</i> . |

The Amihud illiquidity for stock *i* in month *m* is computed as follows: $Illiq_{i,m} = \sum_{d=1}^{n} |R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/|R_{i,m,d}|/$ $(P_{im,d} \times N_{i,m,d}) / n$, where n is the number of trading days in each month m, $|R_{i,m,d}|$ is the absolute value of return of stock i on day d of month m, $P_{i,m,d}$ is the daily closing price of stock i, and $N_{i,m,d}$ is the number of shares of stock i traded during day d, following Amihud (2002). Log(Amihud) refers to the logarithm of Amihud illiquidity.

The proportion of zero daily returns in a month, following Lesmond, Ogden, and Trzcinka (1999). The commonality in liquidity for stock i in month m is computed as follows:

 $\widehat{\omega}_{i,m,d}^{Liq} = \alpha_{i,m}^{Liq} + \sum_{j=-1}^{1} b_{i,m,j}^{Liq} \widehat{\omega}_{M,m,d+j}^{Liq} + \varepsilon_{i,m,d}^{Liq}, \text{ where } \omega_{i,m,d}^{Liq} \text{ is the residual from the following time-series regressions: } Liq_{i,m,d} = \alpha_{i,m}^{Liq} Liq_{i,m,d-1} + \sum_{\tau=1}^{5} \beta_{i,m,\tau}^{Liq} D_{\tau} + \gamma_{i,m}^{Liq} HOLI_{m,d} + \omega_{i,m,d}^{Liq}, \text{ where } Liq_{i,m,d} \text{ is the Amihud liquidity proxy for stock } i \text{ on day } d \text{ of month } m, \text{ defined as } -\log(1 + 1)$ $Illiq_{i,m,d}$), with $Illiq_{i,m,d} = |R_{i,m,d}|/(P_{i,m,d} \times N_{i,m,d})$, all variables are defined as in Log(Amihud), D_{τ} ($\tau = 1, ..., 5$) refers to a list of day-of-the-week dummy variables, and $HOLI_{t,d}$ is a dummy for trading days around non-weekend holidays. $\widehat{\omega}_{M,m,d+j}^{Liq}$ is the market value (at the end of previous year) weighted average of the residuals for all stocks. The R-square $(R_{i,m}^2)$ from the regression measures the commonality in liquidity for stock i of month m. We use the logistic transformation of the Rsquare measures, i.e., $\ln\left(\frac{R_{i,m}^2}{1-R_{i,m}^2}\right)$, following Karolyi, Lee, and van Dijk (2012).

For every stock in each month, we regress daily excess returns on the four domestic factors (market, size, book-to-market and momentum), as well as four foreign factors, defined as the value weighted average of four domestic factors in all remaining countries. /Intercept_8Fac/ is defined as the absolute value of the intercept from this regression for each stock month.

The return co-movement with the global market is defined as the adjusted R-square from the same monthly stock-level regressions as in /Intercept_8Fac/.

The Herfindahl-Hirschman index for mutual fund family F in month m is computed as follows:

 $HHI_{F,m} = \sum_{f \in F} \left(\frac{TNA_{f,m}}{\sum_{f \in F} TNA_{f,m}} \right)^2$, where $TNA_{f,m}$ refers to the total net assets of fund f in month m, and fund f is affiliated with mutual fund family F.

The logarithm of family total net assets (TNA), where the family TNA is computed as the summation of all fund-level TNA (reported in Morningstar) within the family.

The family expense ratio is computed as the fund TNA-weighted annualized expense ratio of all funds within the family, where the TNA values are one-month lagged, and the fund-level expense ratio is reported in Morningstar.

The family turnover is computed as the fund TNA-weighted turnover of all funds within the family, where the TNA values are one-month lagged, and fund-level turnover is reported in Morningstar.

The logarithm of family age, where family age is computed as the fund TNA-weighted number of operational months since inception of all funds within the family, and the fund inception date is reported in Morningstar.

Family return is computed as the fund TNA-weighted return of all funds within the family, where the TNA values are one-month lagged.

The flow for mutual fund family F in month m is computed as follows: $Flow_{F,m} =$ $\sum_{f \in F} [TNA_{f,m} - TNA_{f,m-1} \times (1+R_{f,m})],$ where $TNA_{f,m}$ refers to the total net asset of fund f in month m, $R_{f,m}$

refers to the fund total return in the same month, and fund f is affiliated with mutual fund family F.

The external asset growth for mutual fund family F in year t is computed as follows:

 $EAG_{F,t} = \frac{\sum_{f \in F} [TNA_{f,t} - TNA_{f,t-1} \times (1 + R_{f,t})]}{\sum_{f \in F} TNA_{f,t-1}}, \text{ where } TNA_{f,t} \text{ refers to the total net asset of fund } f \text{ in year } t,$ $R_{f,t} \text{ refers to the cumulative fund total return in the same year, and fund } f \text{ is affiliated with mutual}$ fund family F.

The new fund-implied asset growth for mutual fund family F in year t is computed as follows:

 $EAG_New_{F,t} = \frac{\sum_{f \in F} TNA_{f,t} \times I\{Inception_{f,t}\}}{\sum_{f \in F} TNA_{f,t-1}}, \text{ where } I\{Inception_{f,t}\} \text{ refers to an indicator function that}$ equals one if fund f is launched in year t and zero otherwise, and all other variables are defined as in EAG.

The family external asset growth minus new fund-implied asset growth, and both are defined above.

| ance) | The logarithm of the geographical distance between the target and domicile countries. |
|---------------|--|
| rket Turnover | The total value of shares traded during the year divided by the average market capitalization, as reported by the World Bank. Average market capitalization is calculated as the average of the year- end values for this year and the previous year. |
| rket/GDP | The end-of-year stock market capitalization divided by nominal GDP, as reported by the World Bank. |

| Private Bond Market/GDP | The end-of-year domestic credit value to the private sector divided by nominal GDP, as reported by the World Bank. Domestic credit to the private sector refers to financial resources provided to the private sector by financial corporations. |
|--------------------------------|--|
| HHI_Dom | The Herfindahl-Hirschman index for all funds in the domicile country C in month m is computed as |
| | follows: $HHI_Dom_{C,m} = \sum_{f \in C} \left(\frac{TNA_{f,m}}{\sum_{f \in C} TNA_{f,m}} \right)^2$, where $TNA_{f,m}$ refers to the total net asset of fund f in |
| | month m , and fund f has country C as its domicile country. |
| HHI_Target | The Herfindahl-Hirschman index for all funds in the target country, computed similarly to the <i>HHI_Dom</i> above. |
| Num_Index_Dom | The total number of indices in the domicile country. |
| I. Other Stock Characteristics | |
| Domestic IO (in %) | The domestic mutual fund ownership, computed as the number of shares held by domestic mutual funds divided by the number of shares outstanding. |
| Foreign IO (in %) | The foreign mutual fund ownership, computed as the number of shares held by foreign mutual funds divided by the number of shares outstanding. |
| Stock Return (in %) | The monthly stock return, as reported in Datastream Worldscope. |
| Log (Stock Size) | The logarithm of market capitalization of stocks, in millions, as reported in Datastream Worldscope. |
| Turnover | The monthly stock trading volume scaled by shares outstanding, as reported in Datastream |
| Log (Net Income) | The logarithm of absolute net income, in millions, as reported in Datastream Worldscope, times 1 (- |
| | 1) if net income is positive (negative). |
| Log (Sales) | The logarithm of sales, in millions, as reported in Datastream Worldscope. |
| Log (Total Assets) | The logarithm of total assets, in millions, as reported in Datastream Worldscope. |

Table 1: Summary Statistics

This table presents the summary statistics for the data used in the paper. Panel A reports the mean, median, standard deviation, and the quantile distribution of the number and rank of unexplored indices at the country level and the family level, monthly fund and family return, and other annual family and country characteristics. The sample consists of all mutual fund families with the foreign expansion of active equity mutual funds over the 2001–2012 period. Panel B reports similar statistics for annual market delay, illiquidity, market integration and other stock characteristics. Panel C reports the correlation matrix of the main stock-level dependent and independent variables. Appendix A provides detailed definitions of each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 1—Continued

Table 2: The Decision of Mutual Fund Family Cross-Border Expansion

Panel A presents the results of the following annual logistic or probit regressions with year fixed effects and their corresponding t-statistics with standard errors clustered at the family level,

 $Expansion_{F,C,t} = \alpha + \beta Num_U IT_{C,t-1} + \gamma M_{F,C,t-1} + e_{F,C,t},$ where $Expansion_{F,C,t}$ refers to a dummy variable that equals one if the mutual fund family *F* starts a new foreign fund in target country C in year t and zero otherwise, and $Num_UIT_{C,t-1}$ refers to the number of indices unexplored by foreign mutual funds in target country C. Vector M stacks all other family and target country control variables, including Log(Family TNA), the Expense Ratio, Family Turnover, Log(Family Age), Family Return, Family Flow, Log (Distance), Stock Market Turnover, Stock Market/GDP, Private Bond Market/GDP, return correlation within and outside the family, the Herfindahl index in the domicile country, target country and within fund family, and the number of indices in domicile country. Models 1 to 4 present the results of logistic regressions, while Models 5 to 8 present the results of probit regressions. For Panel B, at the beginning of each year, mutual fund families are sorted into terciles according to their lagged catering incentives, proxied by the number and the rank of unexplored indices at the family level $(Fam_Num_UIT_{F,t-1} \text{ and } Fam_Rank_UIT_{F,t-1})$. We report the holding period (year t) annual expense ratio and turnover, the logarithm of total net assets, and monthly returns for newly launched funds, as well as the annual overall external asset growth rate, new fund-implied asset growth rate and flow-implied asset growth rate. All fund (or family) characteristics are first averaged across funds (families) within the same domicile country and then averaged across countries. The "LMH" rows report the difference in profits between Low and High catering incentive portfolios. Newey-West adjusted t-statistics are shown in parentheses. Our sample includes all active fund expansions. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 2—Continued

Table 3: Performance of Catering-Oriented Cross-Border Expansions

This table presents the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

$Perf_{f,t:t+4} = \alpha + \beta Num_U IT_{f,t-1} + \gamma M_{f,t-1} + e_{f,t},$

where $Perf_{f,t:t+4}$ refers to the average monthly return of fund f in five years (year t to t + 4) after inception, $Num_UIT_{f,t-1}$ refers to the number of index unexplored by foreign mutual funds in the country where fund f is launched, and an alternative measure $Rank_UIT_{f,t-1}$ refers to the rank of unexplored indices. Vector M stacks all other family and target country control variables, including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, Log (Distance), Stock Market Turnover, Stock Market/GDP, Private Bond Market/GDP, return correlation within and outside the family, the Herfindahl index in the domicile country, target country and within fund family, and the number of indices in domicile country. Raw returns are further adjusted by a Fama-French-Carhart four-factor model comprising the market, size, book-to-market, and momentum factors. Our sample includes all newly launched active funds. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 3—Continued

Table 4: Performance of Domestic Funds Managed by Catering-Oriented Families

This table presents the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

$DomPerf_{F,t:t+4} = \alpha + \beta CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t},$

where $DomPerf_{F,t:t+4}$ refers to the average monthly return of the existing domestic portfolios of fund family *F* in five years (year *t* to *t* + 4) after its foreign expansion; in particular, the family domestic return is computed as the lagged TNA-weighted return of all its domestic mutual funds. *CateringIncentive*_{F,t-1} refers to the two measures of catering incentives of a family, including *Fam_Num_UIT*_{F,t-1} (the number of unexplored indices at the family level) and *Fam_Rank_UIT*_{F,t-1} (the rank of unexplored indices at the family level). Vector *M* stacks all other family and domicile country control variables, including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, return correlations within and outside the family, Herfindahl index in domicile country and within fund family, and the number of indices in domicile country. Raw returns are further adjusted by a Fama-French-Carhart four-domestic-factor model comprising the market, size, book-tomarket, and momentum factors. Our sample includes all families that launch active funds in another country. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 5: Performance of Portfolios of Domestic Funds Sorted by Catering Incentives

At the beginning of each year, mutual fund families are sorted into terciles according to their lagged catering incentives, proxied by the number and the rank of unexplored indices at the family level $(Fam_Num_UIT_{F,t-1})$ and $Fam_Rank_UIT_{F,t-1})$. This table reports the holding period (year *t*) monthly returns to the strategy of going long (short) for Low (High) catering incentive families, and the returns are measured by the returns of domestic funds in mutual fund families. The returns are first averaged across fund families within the same domicile country and then averaged across countries. Raw returns are further adjusted by CAPM (the international market factor) or a Fama-French-Carhart four-international-factor model comprising the market, size, book-to-market, and momentum factors. The "LMH" rows report the difference in profits between Low and High catering incentive portfolios. Newey-West adjusted t-statistics are shown in parentheses. Our sample includes all families that launch active funds in another country. Appendix A provides detailed definitions for each variable. Numbers with "*", "**" and "***" are significant at the 10%, 5% and 1% levels, respectively.

Table 6: Robustness Checks for U.S. Mutual Fund Families

This table reports subsample results for U.S. mutual fund families. Models 1 to 2 present the results of the following annual logistic regressions with year fixed effects and their corresponding t-statistics with standard errors clustered at the family level,

 $Expansion_{F,C,t} = \alpha + \beta Num_UIT_{C,t-1} + \gamma M_{F,C,t-1} + e_{F,C,t}$, where all variables are defined as in Table 2. Models 3 to 4 present the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

 $DomPerf_{F,t:t+4} = \alpha + \beta CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t}$, where all variables are defined as in Table 4. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 7: Performance of Foreign Funds Managed by Catering-Oriented Families

Panel A presents the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

$ForPerf_{F,t:t+4} = \alpha + \beta CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t}$

where $ForPerf_{F,t;t+4}$ refers to the average monthly return of the existing foreign portfolios of fund family F in five years (year t to t + 4) after its foreign expansion; in particular, the family foreign return is computed as the lagged TNA-weighted return of all its foreign mutual funds. CateringIncentive_{F,t-1} refers to the two measures of catering incentives of a family, including $Fam_Num_UIT_{F,t-1}$ (the number of unexplored indices at the family level) and $Fam_Rank_UIT_{F,t-1}$ (the rank of unexplored indices at the family level). Vector M stacks all other family and country control variables, including the Herfindahl index in the domicile country and within the fund family, the return correlation within and outside the family, the number of indices in the domicile country, Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), and Family Return. Raw returns are further adjusted by a Fama-French-Carhart four-international-factor model comprising the market, size, book-to-market, and momentum factors. Panel B reports the holding period (year t) monthly returns to the strategy of going long (short) for Low (High) catering incentive families, and the returns are measured by returns of foreign funds in mutual fund families. The portfolio construction is the same as in Table 5, and catering incentive is proxied by the number $(Fam_Num_UIT_{F,t-1})$ and the rank $(Fam_Rank_UIT_{F,t-1})$ of unexplored indices at the family level. Newey-West adjusted t-statistics are shown in parentheses. Our sample includes all families that launch active funds in another country. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 7—Continued

Table 8: Investor Welfare Related to Catering-Oriented Cross-Border Expansions

Models 1 to 6 present the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

$Diversification_{f,t:t+4} = \alpha + \beta Num_UIT_{f,t-1} + \gamma M_{f,t-1} + e_{f,t},$

where *Diversification*_{f,t:t+4} refers to the diversification proxy of fund f in five years (year t to t + t4) after inception, $Num_UIT_{f,t-1}$ refers to the number of indices unexplored by foreign mutual funds in the country where fund f is launched, and an alternative measure $Rank_UIT_{f,t-1}$ refers to the rank of unexplored index. Vector M stacks all other family and target country control variables, including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, Log (Distance), Stock Market Turnover, Stock Market/GDP, Private Bond Market/GDP, return correlation within and outside the family, the Herfindahl index in the domicile country, target country and within fund family, and the number of indices in domicile country. In Models 1 to 2 (Models 3 to 4), the (lack of) diversification is proxied by the return (style-adjusted return) correlation between the newly launched fund and other funds within the same family, and in Models 5 to 6, the correlation is proxied by the return correlation between the newly launched fund and other funds outside the family but in the same domicile country. Models 7 to 8 present the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

 $Perf_{f,t:t+4} = \alpha + \beta Num_UIT_{f,t-1} + \gamma M_{f,t-1} + e_{f,t}$, where $Perf_{f,t:t+4}$ refers to the average monthly four-factor-adjusted return of fund f in five years (year t to t + 4) after inception, computed from a Fama-French-Carhart four-factor model comprising the market, size, book-to-market, and momentum factors. All other variables are defined the same as above, and the analysis is similar to Table 3, while focusing on the sub-period of the 2008 and 2009 financial crisis. Our sample includes all newly launched active funds. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 8—Continued

Table 9: Influence of Catering-Oriented Cross-Border Capital Flows on Stock Market Efficiency

This table presents the results of the following Panel regressions with year and stock fixed effects and their corresponding t-statistics with standard errors clustered at the stock level,

 $Delay_{i,t} = \alpha + \beta CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t},$

where $Delay_{i,t}$ refers to market delay of stock *i* in year *t* to the global market information $(Delay_Global_{i,t})$ or the local market information $(Delay_Local_{i,t})$, and $CateringForOwn_{i,t-1}$ refers to the ownership of catering-oriented active foreign funds either by all foreign funds of catering-oriented families ($CateringForOwnAll_{i,t-1}$) or by newly launched catering-oriented funds (*CateringForOwnNew*_{i,t-1}), as well as the extreme flow-motivated change in ownership of cateringoriented active foreign funds (*CateringForOwnFS*_{i,t-1}). *CateringForOwnAll*_{i,t-1} further refers to a set of variables, i.e., $CateringForOwnAll_Num_{i,t-1}$ and $CateringForOwnAll_Rank_{i,t-1}$ when catering incentives of mutual fund families are proxied by $Fam_Num_UIT_{F,t-1}$ and $Fam_Rank_UIT_{F,t-1}$, respectively. Similarly, *CateringForOwnNew*_{i,t-1} refers to a set of variables, *CateringForOwnNew_Num_{i,t-1}* $CateringForOwnNew_Rank_{i,t-1}$ and i.e., and . CateringForOwnFS_{i,t-1} refers to a set of variables, i.e., CateringForOwnFS_Num_{i,t-1} and CateringForOwnFS_Rank_{i,t-1}. Vector M stacks all other stock and country control variables, including domestic and foreign IO, Stock Return, Log(Stock Size), Turnover, Log(Net Income), Log(Sales), Log(Total Assets), Stock Market Turnover, Stock Market/GDP, and Private Bond Market/GDP. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 9—Continued

Table 10: Influence of Catering-Oriented Cross-Border Capital Flows on Liquidity

This table presents the results of the following Panel regressions with year and stock fixed effects and their corresponding t-statistics with standard errors clustered at the stock level,

 $Illiq_{i,t} = \alpha + \beta CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t},$

where $Illiq_{i,t}$ refers to the illiquidity proxies of stock *i* in year *t*, including the logarithm of Amihud (2002) illiquidity and proportion of zero returns, as well as the proxy for liquidity co-movement. *CateringForOwn*_{*i*,*t*-1} is the ownership of catering-oriented active foreign funds either by all foreign funds of catering-oriented families (*CateringForOwnAll*_{*i*,*t*-1}) or by newly launched catering-oriented funds (*CateringForOwnNew*_{*i*,*t*-1}), as defined in Table 9. Vector *M* stacks all other stock and country control variables, including domestic and foreign IO, Stock Return, Log(Stock Size), Turnover, Log(Net Income), Log(Sales), Log(Total Assets), Stock Market Turnover, Stock Market/GDP, and Private Bond Market/GDP. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table 10—Continued

Table 11: Influence of Catering-Oriented Cross-Border Capital Flows on Stock Market Integration

This table presents the results of the following Panel regressions with year and stock fixed effects and their corresponding t-statistics with standard errors clustered at the stock level,

Integration_{*i*,*t*} = $\alpha + \beta CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t}$,

where $Integration_{i,t}$ refers to the market integration proxies ($/Intercept_8Fac$ / and Co-movement_8Fac) of stock i in year t, $CateringForOwn_{i,t-1}$ is the ownership of catering-oriented active foreign funds either by all foreign funds of catering-oriented families ($CateringForOwnAll_{i,t-1}$) or by newly launched catering-oriented funds ($CateringForOwnNew_{i,t-1}$), as defined in Table 9. Vector M stacks all other stock and country control variables, including domestic and foreign IO, Stock Return, Log(Stock Size), Turnover, Log(Net Income), Log(Sales), Log(Total Assets), Stock Market Turnover, Stock Market/GDP, and Private Bond Market/GDP. The integration is defined with respect to Fama-French-Carhart four domestic factors (market, size, book-to-market, and momentum) and four foreign factors (value-weighted four factors excluding the domestic country). Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Figure 1: Number of Stock Market Indices and Size of the Global Mutual Fund Industry

This figure plots the number of stock market indices explored by the global mutual fund industry, as well as the total net assets (TNA, indicated by the left axis in billions USD) and number of mutual funds from 2000 to 2012. The number of mutual funds and stock market indices are indicated by the right axis.

Internet Appendix

Does Financial Globalization Propagate Managerial Skills? Lessons from the Mutual Fund Industry

In this Internet Appendix, we provide two sets of robustness tests of the main results. First, we confirm our main findings on mutual fund family skills in the full sample and in a sub-sample excluding the closet indexers, and we employ alternative performance measures. Next, we conduct robustness tests regarding the market influence of cross-border capital flows from three dimensions: informational efficiency, liquidity, and market integration. We adopt placebo tests to confirm our main results and exclude the closet indexers in our analyses.

Table IA1 tabulate the summary statistics for the full sample, and the distribution is largely similar to that of active funds. Table IA2 investigates the subsequent performance of newly launched funds after cross-border expansion. Panel A includes all (both active and passive) fund expansions and suggests that new funds launched for catering purposes perform poorly in the subsequent five years after inception. In particular, a one-standard-deviation increase in the number (rank) of unexplored indices reduces annual returns and risk-adjusted performance by 0.31% and 1.33% (0.34% and 0.92%) in the overall sample. Moreover, Cremers, Ferreira, Matos, and Starks (2016) document that some active funds are largely passively managed, and these closet indexers manage approximately 20% of the worldwide mutual fund assets. In Panel B, we further exclude the closet indexers, defined as funds with an active share below 60% (following Cremers and Petajisto (2009) and Cremers, Ferreira, Matos, and Starks (2016)). The results show a similar statistical and economic impact.

Panels C and D of Table IA2 examine alternative performance measures. Panel C constructs *New Fund 8-Factor-adjusted Return*, computed from an 8-factor model, including four Fama-French-Carhart (FFC) factors (market, size, book-to-market, and momentum) measured in the target country where the new fund is launched, as well as four foreign factors, that is, the value weighted average of the four factors in all other countries. Our main results are robust to this alternative performance measure for both the active funds sample and the full sample. While thus far we have focused on the net return delivered to mutual fund investors after all fees and expenses, Panel D employs gross-of-fee performance of newly launched active funds. Gross-of-fee fund return is computed as the fund total return plus one-twelfth of the annualized expense ratio, and gross-of-fee fund returns are further adjusted by a Fama-French-Carhart four-factor model. The results confirm that the fund performance is significantly worse after catering-oriented cross-border expansions, even on a gross-of-fee basis. A one-standard-deviation increase in the number (rank) of unexplored indices reduces annual returns and risk-adjusted gross-of-fee performance by 0.31% and 1.43% (0.26% and 0.87%). Overall, our findings imply that the cross-border expansion of mutual fund families due to catering incentives is associated with lower performance.

Next, we investigate whether catering-oriented overseas expansions are related to the managerial skills of the mutual fund families, proxied by the family performance in both the domestic and the foreign market. We first re-estimate the same specifications as Equations (6) and (7), and the results are reported in Table IA3. Panel A includes all families with overseas expansion, with Models (1) to (4) focusing on domestic performance and Models (5) to (10) focusing on foreign performance. Foreign performance is adjusted by an international Fama-French-Carhart four-factor model and an 8-factor model consisting of four domestic factors and four foreign factors, which are the value weighted average of four domestic factors in all other countries. A one-standard-deviation increase in the number (rank) of unexplored indices reduces returns and FFC four-factor-adjusted performance by 0.43% and 0.35% (0.48% and 0.34%) per year in the domestic market and by 0.26% and 0.26% (0.27% and 0.2%) per year in the foreign market. To better understand the economic magnitude, we also perform a portfoliobased analysis. Unreported results show that the families with high catering incentives underperform those with low catering incentives by 2.78% (2.77%) per year in FFC four-factor alpha in the domestic market and by 2.81% (3.11%) in the foreign market when catering incentive is proxied by the number (rank) of unexplored indices. Panel B reports similar statistics in a sub-sample excluding closet indexers and confirms the negative relationship between mutual fund catering incentives and its performance. For instance, a one-standard-deviation increase in the rank of unexplored indices reduces returns (FFC four-factor alpha) by 0.29% (0.19%) per year in the domestic market and by 0.19% (0.13%) per year in the foreign market. In addition, Panel C constructs gross-of-fee family performance for all families that launch active funds in another country. Gross-of-fee family domestic (foreign) return is computed as the lagged TNA-weighted gross-of-fee return of all its domestic (foreign) mutual funds. Gross-of-fee family returns are further adjusted by a Fama-French-Carhart four-factor model and an 8-factor model. A one-standard-deviation increase in the rank of unexplored indices reduces gross-of-fee FFC fourfactor alpha by 0.22% per year in the domestic market and by 0.15% per year in the foreign market. To conclude, we provide evidence that catering-oriented mutual fund families appear to be low-skilled and underperform in both the domestic and foreign markets. The results are robust to alternative samples and performance measures.

We move on to examine the relation between informational efficiency and the ownership of actively managed foreign funds offered by catering-oriented and non-catering-oriented fund families. Unlike in Table 9, we further include the ownership of non-catering-oriented active foreign funds as a placebo test. Empirically, mutual fund families are sorted into terciles within the domicile country, according to their lagged catering incentives, proxied by the number and the rank of unexplored indices at the family level (Fam_Num_UIT and Fam_Rank_UIT). Those in the top (bottom) tercile are defined as cateringoriented (non-catering-oriented) families. We then aggregate the ownership of non-catering-oriented active foreign funds either by all foreign funds of non-catering-oriented families (Non-CateringForOwnAll) or by newly launched non-catering-oriented funds (Non-CateringForOwnNew). We also include the extreme flow-motivated change in ownership of non-catering-oriented active foreign funds (Non-CateringForOwnFS). Non-CateringForOwnAll (Non-CateringForOwnNew, Non-CateringForOwnFS) further refers to a set of variables, i.e., Non-CateringForOwnAll Num and Non-CateringForOwnAll_Rank (Non-CateringForOwnNew_Num and Non-CateringForOwnNew_Rank, Non-CateringForOwnFS_Num and Non-CateringForOwnFS_Rank) when catering incentive is proxied by Fam_Num_UIT and Fam_Rank_UIT, respectively. The results are reported in Table IA4, and only the main variables are tabulated for brevity. In Panel A, the informational efficiency is proxied by price delay to global and local market information, following Bae, Ozoguz, Tan, and Wirjanto (2012), as defined in Table 9 and Appendix A. In Panel B, we consider alternative measures of market efficiency. We first compute the *Variance Ratio* for stock *i* in year *t* as follows:

$$VR_{i,t} = \left| \frac{VAR5_{i,t}}{5 \times VAR1_{i,t}} - 1 \right|,\tag{A1}$$

where $VAR5_{i,t}$ and $VAR1_{i,t}$ refer to the variance of five-week and one-week accumulated returns of stock *i* in year *t*, following Griffin, Kelly, and Nardari (2010).

The second proxy – *Market Delay* – for stock *i* in year *t* is defined as follows:

$$Delay_{i,t} = 1 - \frac{R_{restricted,i,t}^2}{R_{unrestricted,i,t}^2},$$
(A2)

Internet Appendix Page 4

where $R_{restricted,i,t}^2$ and $R_{unrestricted,i,t}^2$ refer to the adjusted R-square from restricted and unrestricted market models estimated using weekly returns in each year t. The restricted model (RM) and unrestricted model (UM) are defined, respectively, as follows:

$$RM: R_{i,w,t} = \alpha_i + \beta_{0,i}R_{mkt,w,t} + e_{i,w,t}, \tag{A3}$$

$$UM: R_{i,w,t} = \alpha_i + \sum_{k=0}^4 \beta_{i,k,t} R_{mkt,w-k,t} + e_{i,w,t},$$
(A4)

where $R_{i,w,t}$ refers to the accumulated return of stock *i* in week *w* of year *t*, and $R_{mkt,w,t}$ refers to the value-weighted market return in the same week, following Mech (1993), Hou and Moskowitz (2005), and Griffin, Kelly, and Nardari (2010).

In line with the findings in Table 9, the results in Panel A suggest that the capital flows associated with catering-oriented cross-border expansions do not improve the price discovery in terms of incorporating both global and local market news. For instance, a one-standard-deviation increase in the ownership of catering-oriented foreign funds identified based on the number (rank) of unexplored indices is related to 1.33% (1.35%) greater price delay (i.e., the influence of additional price delay scaled by the standard deviation of price delay) to the global market information and 0.96% (0.99%) greater price delay to the local market information. However, the cross-border expansions from skilled (least-catering-oriented or non-catering-oriented) foreign funds indeed improve the overall market efficiency in the target country by reducing the price delay to both global and local market information. A one-standard-deviation increase in the ownership of non-catering-oriented foreign funds identified based on the number (rank) of unexplored indices is related to 0.84% (0.68%) less price delay to the global market information. The results are robust to alternative measures of ownership when focusing only on newly launched funds.

To further alleviate potential concerns of endogeneity, we investigate the exogenous change in foreign ownership using flow-induced mutual fund transactions, i.e., fire sales and fire purchases (Coval and Stafford (2007)). Since mutual funds usually do not maintain significant cash balances given the equity benchmarks they track and rarely take short positions, when outside investors withdraw their capital and mutual funds experience extreme outflows, mutual fund managers are forced to sell some of existing holdings to cover redemptions. Therefore, the extreme flow-motivated ownership change is

driven by idiosyncratic fund-level liquidity shocks instead of certain stock characteristics. As a result, fire sales experienced by individual funds introduce plausibly exogenous shocks into their ownership (e.g., Coval and Stafford, 2007; Jotikasthira, Lundblad, and Ramadorai, 2012), which are unlikely to be directly related to the price efficiency of the fund investing country except through the investment behavior of these funds. The empirical evidence suggest that exogenous exit of catering-oriented foreign funds reduces the price delay to both global and local market information and improves the overall market efficiency in the target country. On the other hand, fire sale flows of least catering-oriented funds are no longer beneficial – they become largely statistically insignificant. Intuitively, such trades are not information-driven and even funds with the proper incentives may not benefit the investing country when these funds are themselves in trouble. The results are also robust to alternative measures of market efficiency in Panel B. Hence, the harmful impact really comes from catering-oriented and low-skilled foreign expansions.

Since the emerging markets have a generally more opaque information environment and are less efficient than developed markets, catering-oriented overseas expansions can be more detrimental to emerging markets. To formally test this notion, we apply the analyses in Panel A to a sub-sample of emerging markets and report the findings in Panel C. The classification of emerging markets follows Griffin, Kelly, and Nardari (2010). The results suggest that the catering incentives contribute to the price delay in emerging markets only, and a one-standard-deviation increase in ownership of catering-oriented foreign funds (none-catering funds) is associated with 3.63% greater (2.37% less) price delay with respect to global market information and with 2.82% greater (2.07% less) price delay with respect to local market information. Therefore, catering-oriented foreign capital flows could reduce price efficiency by approximately 4.9% to 6% than non-catering-oriented foreign capital flows.

Next, we relate catering incentives to stock liquidity and commonality in liquidity. Controlling for the ownership of non-catering-oriented active foreign funds, Table IA5 Panel A provides supporting evidence that catering-oriented foreign capital flows do not improve liquidity but increase the commonality in liquidity. In contrast, skilled (least-catering-oriented) foreign funds display a similar pattern and fail to provide liquidity in the target country. Similarly, we assess whether catering incentives affect market integration. The tests closely follow Table 11, while we further employ the

Internet Appendix Page 6

ownership of non-catering-oriented active foreign funds as a placebo test. The results in Panel B suggest that catering-oriented foreign ownership in general is uncorrelated with integration with respect to the overall international market factors.

Finally, we show that the market influence of cross-border capital flows on informational efficiency, liquidity, and market integration still holds when we exclude closet indexers. The results are reported in Table IA6. Panel A confirms that price delay to both global and local market information is enhanced after catering-oriented cross-border expansions. In particular, a one-standard-deviation increase in ownership of catering-oriented foreign funds identified based on the number (rank) of unexplored indices is related to 1.28% (1.19%) greater price delay (i.e., the influence of additional price delay scaled by the standard deviation of price delay) to the global market information and 0.92% (0.89%) greater price delay to the local market information. In terms of liquidity conditions, the findings in Panel B suggest that catering-oriented foreign capital flows do not improve the stock liquidity in the target country but lead to higher commonality in liquidity. A one-standard-deviation increase in the ownership of catering-oriented foreign funds identified based on the number (rank) of unexplored indices is associated with an increase in Amihud *illiquidity* by 0.41% (0.4%), the proportion of zero return days by 1.32% (1.31%), and commonality in liquidity with respect to the local market by 0.97% (0.96%, all scaled by the standard deviation of illiquidity or liquidity commonality measures). In addition, the results for market integration are tabulated in Panel C. We find confirming evidence that cateringoriented foreign ownership is not related to integration with respect to the overall international market factors.

In conclusion, our findings are robust to the alternative definition of active funds, i.e., based on 60% active share breakpoint, following Cremers and Petajisto (2009) and Cremers, Ferreira, Matos, and Starks (2016). Low-skilled fund companies are likely to adopt catering-oriented overseas expansions to differentiate their products and attract global style-investors to invest in their new funds, and such expansions are associated with low performance for all categories of funds that a family offers. In addition, catering-oriented cross-border capital flows reduce both price efficiency and liquidity conditions.

Table IA1: Summary Statistics

This table presents the summary statistics for the data used in the paper, including the mean, median, standard deviation, and the quantile distribution of number and rank of unexplored index at the country level as well as family level, monthly fund and family return, and other annual family and country characteristics. The sample consists of all mutual fund families with foreign expansion of all equity mutual funds over the period 2001–2012. Appendix A provides detailed definitions of each variable.

| Quantile Distribution of Family and Country Characteristics (All Funds) | | | | | | | | | | |
|---|---------|----------|-----------------------|---------|---------|---------|---------|--|--|--|
| | | 0.10 | Quantile Distribution | | | | | | | |

Table IA2: Performance of Catering-Oriented Cross-Border Expansions

This table presents the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

$Perf_{f,t:t+4} = \alpha + \beta Num_UIT_{f,t-1} + \gamma M_{f,t-1} + e_{f,t},$

where $Perf_{f,t:t+4}$ refers to the average monthly return of fund f in five years (year t to t + 4) after inception, $Num_UIT_{f,t-1}$ refers to the number of index unexplored by foreign mutual funds in the country where fund f is launched, and an alternative measure $Rank_UIT_{f,t-1}$ refers to the rank of unexplored index. Vector M stacks all other family and target country control variables, including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, Log (Distance), Stock Market Turnover, Stock Market/GDP, Private Bond Market/GDP, return correlation within and outside family, the Herfindahl index in the domicile country, target country and within fund family, and the number of indices in domicile country. Raw returns are further adjusted by a Fama-French-Carhart four-factor model comprising the market, size, book-to-market, and momentum factors. Panel A includes all newly launched funds, and Panel B includes all newly launched active funds – defined as those with active share no less than 60% (following Cremers and Petajisto (2009) and Cremers, Ferreira, Matos, and Starks (2016)). Panel C reports similar statistics when raw returns are adjusted by an 8factor model including four Fama-French-Carhart factors in the target country where the new fund is launched, as well as four foreign factors that are the value weighted average of the four factors in all other countries. Panel D reports similar statistics when we focus on gross-of-fee performance of newly launched active funds. Gross-of-fee fund return refers to the fund total return plus one-twelfth of the annualized expense ratio, and gross-of-fee fund returns are further adjusted by a Fama-French-Carhart four-factor model. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

| | New Fu | nd Return | New Fund 4-H | Factor-adjusted |

Table IA3: Performance of Domestic and Foreign Funds Managed by Catering-**Oriented Families**

Panel A Models 1 to 4 present the results of the following regressions with year fixed effects and their corresponding robust t-statistics,

 $DomPerf_{F,t:t+4} = \alpha + \beta CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t}$ where $DomPerf_{F,t;t+4}$ refers to the average monthly return of the existing domestic portfolios of fund family F in five years (year t to t + 4) after its foreign expansion, and in particular the family domestic return is computed as the lagged TNA-weighted return of all its domestic mutual funds. CateringIncentive_{F,t-1} refers to the two measures of catering incentives of a family, including $Fam_Num_UIT_{F,t-1}$ (the number of unexplored index at the family level) and $Fam_Rank_UIT_{F,t-1}$ (the rank of unexplored index at the family level). Vector M stacks all other family and domicile country control variables, including Log(Family TNA), Expense Ratio, Family Turnover, Log(Family Age), Family Return, return correlation within and outside family, Herfindahl index in domicile country and within fund family, and number of indices in domicile country. Raw returns are further adjusted by a Fama-French-Carhart four-domestic-factor model comprising the market, size, book-to-market, and momentum factors. Models 5 to 10 present similar statistics of the following regressions,

 $ForPerf_{F,t:t+4} = \alpha + \beta CateringIncentive_{F,t-1} + \gamma M_{F,t-1} + e_{F,t}$, where $ForPerf_{F,t:t+4}$ refers to the average monthly return of the existing foreign portfolios of fund family F in five years (year t to t + 4) after its foreign expansion, and in particular the family foreign return is computed as the lagged TNA-weighted return of all its foreign mutual funds. All other variables are defined as above. Raw returns are also adjusted by an 8-factor model including Fama-French-Carhart four domestic factors, as well as four foreign factors that are the value weighted average of the four factors in all other countries. Our sample includes all families that launch funds in another country. Panel B reports similar statistics for all families that launch active funds in another country, and active funds are defined as those with active share no less than 60% (following Cremers and Petajisto (2009) and Cremers, Ferreira, Matos, and Starks (2016)). Panel C reports similar statistics when we focus on gross-of-fee family performance for all families that launch active funds in another country. Gross-offee fund return refers to the fund total return plus one-twelfth of the annualized expense ratio, and grossof-fee family domestic (foreign) return is computed as the lagged TNA-weighted gross-of-fee return of all its domestic (foreign) mutual funds. Gross-of-fee family returns are further adjusted by a Fama-French-Carhart four-factor model. Appendix A provides detailed definitions for each variable. Numbers with "*", "**" and "***" are significant at the 10%, 5% and 1% level, respectively.

Table IA3—Continued

Table IA4: Influence of Catering-Oriented Cross-Border Capital Flows on Stock Market Efficiency

Panel A presents the results of the following Panel regressions with year and stock fixed effects and their corresponding t-statistics with standard errors clustered at the stock level,

 $Delay_{i,t} = \alpha + \beta_1 CateringForOwn_{i,t-1} + \beta_2 NonCateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t}$ where $Delay_{i,t}$ refers to market delay of stock i in year t to the global market information $(Delay_Global_{i,t})$ or the local market information $(Delay_Local_{i,t})$, $CateringForOwn_{i,t-1}$ and NonCateringForOwn_{i,t-1} refer to the ownership of catering-oriented and non-catering-oriented active foreign funds either by all foreign funds ($CateringForOwnAll_{i,t-1}$ and NonCateringForOwnAll_{it-1}) or by newly launched funds (CateringForOwnNew_{i,t-1} and NonCateringForOwnNew_{i,t-1}), as well as the extreme flow-motivated change in ownership of catering-oriented and non-catering-oriented active foreign funds ($CateringForOwnFS_{i,t-1}$ and NonCateringForOwnFS_{i,t-1}). Mutual fund families are sorted into terciles within the domicile country according to their lagged catering incentives, proxied by the number and the rank of unexplored index at the family level ($Fam_Num_UIT_{F,t-1}$ and $Fam_Rank_UIT_{F,t-1}$). Those in the top (bottom) tercile are defined as catering-oriented (non-catering-oriented) families. CateringForOwnAll_{i,t-1} (*CateringForOwnNew*_{i,t-1}, *CateringForOwnFS*_{i,t-1}) further refers to a set of variables, i.e., CateringForOwnAll_Num_{i.t-1} and *CateringForOwnAll_Rank*_{*i*,*t*-1}

($CateringForOwnNew_Num_{i,t-1}$ and $CateringForOwnNew_Rank_{i,t-1}$, $CateringForOwnFS_Num_{i,t-1}$ and $CateringForOwnFS_Rank_{i,t-1}$) when catering incentives of mutual fund families are proxied by $Fam_Num_UIT_{F,t-1}$ and $Fam_Rank_UIT_{F,t-1}$, respectively. Similar definitions also apply to $NonCateringForOwnAll_{i,t-1}$, $NonCateringForOwnNew_{i,t-1}$, and $NonCateringForOwnFS_{i,t-1}$. Vector M stacks all other stock and country control variables, including domestic and foreign IO, Stock Return, Log(Stock Size), Turnover, Log(Net Income), Log(Sales), Log(Total Assets), Stock Market Turnover, Stock Market/GDP, and Private Bond Market/GDP. Panel B reports similar statistics when dependent variables are replaced with *Variance Ratio* and *Market Delay*. Panel C reports similar statistics as in Panel A for sub-samples of emerging markets. Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table IA4—Continued

Table IA5: Influence of Catering-Oriented Cross-Border Capital Flows on Liquidity and Stock Market Integration

Panel A presents the results of the following Panel regressions with year and stock fixed effects and their corresponding t-statistics with standard errors clustered at the stock level,

 $Illiq_{i,t} = \alpha + \beta_1 CateringForOwn_{i,t-1} + \beta_2 NonCateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t}$, where $Illiq_{i,t}$ refers to the illiquidity proxies of stock *i* in year *t*, including the logarithm of Amihud (2002) illiquidity and proportion of zero returns, as well as the proxy for liquidity co-movement. *CateringForOwn*_{i,t-1} and *NonCateringForOwn*_{i,t-1} refer to the ownership of catering-oriented and non-catering-oriented active foreign funds either by all foreign funds (*CateringForOwnAll*_{i,t-1} and *NonCateringForOwnAll*_{i,t-1}) or by newly launched funds (*CateringForOwnNew*_{i,t-1} and *NonCateringForOwnNew*_{i,t-1}), as defined in Table IA4. Vector *M* stacks all other stock and country control variables, including domestic and foreign IO, Stock Return, Log(Stock Size), Turnover, Log(Net Income), Log(Sales), Log(Total Assets), Stock Market Turnover, Stock Market/GDP, and Private Bond Market/GDP. Panel B reports similar statistics of the following Panel regressions,

Integration_{*i*,*t*} = $\alpha + \beta_1 CateringForOwn_{i,t-1} + \beta_2 NonCateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t}$, where Integration_{*i*,*t*} refers to the market integration proxies (/Intercept_8Fac/ and Comovement_8Fac) of stock *i* in year *t*, and all other variables are defined as above. The integration is defined with respect to Fama-French-Carhart four domestic factors (market, size, book-to-market, and momentum) and four foreign factors (value-weighted four factors excluding the domestic country). Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.

Table IA6: Influence of Catering-Oriented Cross-Border Capital Flows (Exclude Closet Indexers)

Panel A presents the results of the following Panel regressions with year and stock fixed effects and their corresponding t-statistics with standard errors clustered at the stock level,

 $Delay_{i,t} = \alpha + \beta CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t},$

where $Delay_{i,t}$ refers to market delay of stock *i* in year *t* to the global market information $(Delay_Global_{i,t})$ or the local market information $(Delay_Local_{i,t})$. CateringForOwn_{i,t-1} and NonCateringForOwn_{i,t-1} refer to the ownership of catering-oriented and non-catering-oriented active foreign funds either by all foreign funds $(CateringForOwnAll_{i,t-1})$ or by newly launched funds $(CateringForOwnNew_{i,t-1})$ and NonCateringForOwnNew_{i,t-1}), as defined in Table IA4. Vector *M* stacks all other stock and country control variables, including domestic and foreign IO, Stock Return, Log(Stock Size), Turnover, Log(Net Income), Log(Sales), Log(Total Assets), Stock Market Turnover, Stock Market/GDP, and Private Bond Market/GDP. Panel B reports similar statistics of the following Panel regressions,

 $Illiq_{i,t} = \alpha + \beta CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t},$

where $Illiq_{i,t}$ refers to the illiquidity proxies of stock *i* in year *t*, including the logarithm of Amihud (2002) illiquidity and proportion of zero returns, as well as the proxy for liquidity co-movement, and all other variables are defined as above. Panel C reports similar statistics of the following Panel regressions,

 $Integration_{i,t} = \alpha + \beta CateringForOwn_{i,t-1} + \gamma M_{i,t-1} + e_{i,t},$

where $Integration_{i,t}$ refers to the market integration proxies (/Intercept_8Fac/ and Co-movement_8Fac) of stock *i* in year *t*, and all other variables are defined as above. The integration is defined with respect to Fama-French-Carhart four domestic factors (market, size, book-to-market, and momentum) and four foreign factors (value-weighted four factors excluding the domestic country). Active funds are defined as those with active share no less than 60%, following Cremers and Petajisto (2009) and Cremers, Ferreira, Matos, and Starks (2016). Appendix A provides detailed definitions for each variable. Numbers with "*", "**", and "***" are significant at the 10%, 5%, and 1% levels, respectively.
