Motivation: biased beliefs

- ▶ Beliefs are key to economic and financial decisions

Motivation: biased beliefs

- ▶ Beliefs are key to economic and financial decisions
- ▶ Traditional models assume Full Information Rational Expectations (FIRE)

Motivation: biased beliefs

- ▶ Beliefs are key to economic and financial decisions
- ▶ Traditional models assume Full Information Rational Expectations (FIRE)
- ▶ But,
 - ① deviations from FIRE have been documented in various forms
 - return extrapolation, diagnostic expectations, overconfidence, ...
 - ② biased beliefs affect choice across many decision domains
 - individual trading, corporate investment, bank loans, ...
 - asset prices and the macroeconomy

Motivation: biased beliefs

- ▶ Beliefs are key to economic and financial decisions
- ▶ Traditional models assume Full Information Rational Expectations (FIRE)
- ▶ But,
 - ① deviations from FIRE have been documented in various forms
 - return extrapolation, diagnostic expectations, overconfidence, ...
 - ② biased beliefs affect choice across many decision domains
 - individual trading, corporate investment, bank loans, ...
 - asset prices and the macroeconomy
- ▶ The underlying sources of biased beliefs are less well understood
 - psychological flaws, bounded rationality, informational frictions, ...

Motivation: memory

- ▶ A budding theory literature shows that features of human memory can help reconcile puzzles about beliefs and choice (e.g., Wachter and Kahana, 2021; Bordalo et al., 2022b)

Motivation: memory

- ▶ A budding theory literature shows that features of human memory can help reconcile puzzles about beliefs and choice (e.g., Wachter and Kahana, 2021; Bordalo et al., 2022b)
- ▶ Key mechanism: *similarity*-based recall
 - ① **selective**: not all experiences enter memory; not all memories are retrieved
 - ② **cued**: external cues trigger recall of past experiences associated with *similar* cues

Motivation: memory

- ▶ A budding theory literature shows that features of human memory can help reconcile puzzles about beliefs and choice (e.g., Wachter and Kahana, 2021; Bordalo et al., 2022b)
- ▶ Key mechanism: *similarity*-based recall
 - ① **selective**: not all experiences enter memory; not all memories are retrieved
 - ② **cued**: external cues trigger recall of past experiences associated with *similar* cues
- ▶ Memory research has examined this mechanism extensively in the lab (Kahana, 2012)
 - additional lab evidence from economic settings (Enke et al., 2020; Bordalo et al., 2022b; Graeber et al., 2022)

Motivation: memory

- ▶ A budding theory literature shows that features of human memory can help reconcile puzzles about beliefs and choice (e.g., Wachter and Kahana, 2021; Bordalo et al., 2022b)
- ▶ Key mechanism: *similarity*-based recall
 - ① **selective**: not all experiences enter memory; not all memories are retrieved
 - ② **cued**: external cues trigger recall of past experiences associated with *similar* cues
- ▶ Memory research has examined this mechanism extensively in the lab (Kahana, 2012)
 - additional lab evidence from economic settings (Enke et al., 2020; Bordalo et al., 2022b; Graeber et al., 2022)
- ▶ But, there have been few studies that directly test this mechanism using field data

This paper

- ▶ We survey a nationally representative sample of $\sim 17K$ Chinese individual investors
 - two types of recall
 - ① a market episode that first comes to mind: free recall
 - ② own performance during pre-specific periods in the past: probed recall
 - investor expectations and other individual information
- ▶ Survey data are merged with administrative data of detailed transactions ($\sim 5K$) at one of the largest financial institution in China.

This paper

- ▶ We survey a nationally representative sample of $\sim 17K$ Chinese individual investors
 - two types of recall
 - ① a market episode that first comes to mind: free recall
 - ② own performance during pre-specific periods in the past: probed recall
 - investor expectations and other individual information
- ▶ Survey data are merged with administrative data of detailed transactions ($\sim 5K$) at one of the largest financial institutions in China.
- ▶ We use elicited recalls to document stylized facts about investor memory and the relationship between memory and beliefs.

This paper

- ▶ We survey a nationally representative sample of $\sim 17K$ Chinese individual investors
 - two types of recall
 - ① a market episode that first comes to mind: free recall
 - ② own performance during pre-specific periods in the past: probed recall
 - investor expectations and other individual information
- ▶ Survey data are merged with administrative data of detailed transactions ($\sim 5K$) at one of the largest financial institution in China.
- ▶ We use elicited recalls to document stylized facts about investor memory and the relationship between memory and beliefs.
- ▶ Our setting is different from those in existing studies
 - ① **sample pool**: retail investors (some of which are rather affluent)
 - ② **decision domain**: high-stake (trading of stocks)
 - ③ **cue**: market-based cues such as return
 - ④ **rational benchmark**: direct observations of actual trading records

Main results

We present and test a model of belief formation based on cued recall (Bordalo et al., 2022a)

- ① *Recall*: present cues trigger recall of past experiences
- ② *Simulation*: use retrieved experiences to make forecasts

Main results

We present and test a model of belief formation based on cued recall (Bordalo et al., 2022a)

- ① Market fluctuations affect investors' recall process
 - when recent returns have been high, investors tend to
 - think of episodes of a **rising** market
 - recall their own past performances more **positively**
 - cued recall is stronger for more **recent** experiences

Main results

We present and test a model of belief formation based on cued recall (Bordalo et al., 2022a)

- ① Market fluctuations affect investors' recall process
- ② Investors use retrieved memories to form expectations
 - a positive and robust relationship between memory and expected future returns.
 - **recalled own return** \approx **individual characteristics** (including demographics) in their explanatory power for return expectations

Main results

We present and test a model of belief formation based on cued recall (Bordalo et al., 2022a)

- ① Market fluctuations affect investors' recall process
- ② Investors use retrieved memories to form expectations
- ③ Cued recall *can* microfound return extrapolation
 - return extrapolation: **good** returns → **optimistic** expectations
 - cued recall: **good** returns → **positive** recalls → **optimistic** expectations
 - controlling for recalls **drives out** the positive correlation between recent returns and expectations
 - **rule in** a memory-based microfoundation for return extrapolation

A Conceptual Framework

Model setup

- ▶ In period T , an investor makes forecasts about the next period's market return, r_{T+1} , in two steps:
 - ① *recall*: retrieve past experiences
 - ② *simulation*: use retrieved experiences to forecast the future

Model setup

- ▶ In period T , an investor makes forecasts about the next period's market return, r_{T+1} , in two steps:
 - ① *recall*: retrieve past experiences
 - ② *simulation*: use retrieved experiences to forecast the future

Step 1: Recall

- ▶ In period $t (\leq T - 1)$, she accumulated a “database” of experiences in the stock market, summarized by e_t
 - each experience could have multiple attributes (time, location, context, return, ...)

Model setup

- ▶ In period T , an investor makes forecasts about the next period's market return, r_{T+1} , in two steps:
 - ① *recall*: retrieve past experiences
 - ② *simulation*: use retrieved experiences to forecast the future

Step 1: Recall

- ▶ In period $t (\leq T - 1)$, she accumulated a “database” of experiences in the stock market, summarized by e_t
 - each experience could have multiple attributes (time, location, context, return, ...)
- ▶ For simplicity, we assume each experience only concerns return: $e_t = r_t$
 - r_t consists of a continuum of numbers

Model setup

- ▶ In period T , an investor makes forecasts about the next period's market return, r_{T+1} , in two steps:
 - ① *recall*: retrieve past experiences
 - ② *simulation*: use retrieved experiences to forecast the future

Step 1: Recall

- ▶ In period $t (\leq T - 1)$, she accumulated a “database” of experiences in the stock market, summarized by e_t
 - each experience could have multiple attributes (time, location, context, return, ...)
- ▶ For simplicity, we assume each experience only concerns return: $e_t = r_t$
 - r_t consists of a continuum of numbers
- ▶ Assume that r_t is normally distributed: $r_t \sim N(\mu_t, \sigma_t^2)$
 - objective description of past experiences: in period t , she experienced a market return of x with probability $f_t(x)$

Cued recall

No cue

- ▶ Recall means taking random draws according to the original PDF f_t

With cue

- ▶ An external stimulus, q_T , affects recall according to the rule of **similarity**: experiences with attributes **similar** to q_T are more likely to be recalled

Cued recall

No cue

- ▶ Recall means taking random draws according to the original PDF f_t

With cue

- ▶ An external stimulus, q_T , affects recall according to the rule of **similarity**: experiences with attributes **similar** to q_T are more likely to be recalled
- ▶ Specifically:

$$f^*(r_t; q_T) = f_t(r_t) \times \frac{s(r_t, q_T)}{\int_{-\infty}^{+\infty} f(z) \times s(z, q_T) dz}$$

where $s(r_t, q_T)$ denotes the similarity between cue q_T and experience r_t

When $q_T = r_T$

- ▶ Assume that

$$s(r_t, r_T) = \exp\left(-\frac{(r_t - r_T)^2}{2\tau\sigma_\epsilon^2}\right)$$

- $\tau = T - t$ is the time elapsed since the experienced return
- σ_ϵ is the perceived relevance of the cue

When $q_T = r_T$

- ▶ Assume that

$$s(r_t, r_T) = \exp\left(-\frac{(r_t - r_T)^2}{2\tau\sigma_\epsilon^2}\right)$$

- $\tau = T - t$ is the time elapsed since the experienced return
- σ_ϵ is the perceived relevance of the cue

- ▶ Recalled returns follows a “cued” normal distribution

$$r_t | r_T \sim N((1 - \alpha)\mu_t + \alpha r_T, \sigma_q^2)$$

where

$$\alpha = \frac{\sigma_t^2}{\sigma_t^2 + \tau\sigma_\epsilon^2}$$

When $q_T = r_T$

- ▶ Assume that

$$s(r_t, r_T) = \exp\left(-\frac{(r_t - r_T)^2}{2\tau\sigma_\epsilon^2}\right)$$

- $\tau = T - t$ is the time elapsed since the experienced return
- σ_ϵ is the perceived relevance of the cue

- ▶ Recalled returns follows a “cued” normal distribution

$$r_t | r_T \sim N((1 - \alpha)\mu_t + \alpha r_T, \sigma_q^2)$$

where

$$\alpha = \frac{\sigma_t^2}{\sigma_t^2 + \tau\sigma_\epsilon^2}$$

- ▶ This is equivalent to the investor using the current return r_T as a signal to infer r_t in a Bayesian fashion, by assuming that $r_T = r_t + \epsilon_\tau$

Model results: recall

Hypothesis 1. (*Cued recall*) *The mean of recalled returns, $\mathbb{E}[r_t|r_T] = (1 - \alpha)\mu_t + \alpha r_T$, increases in today's market return r_T .*

Model results: recall

Hypothesis 1. *(Cued recall) The mean of recalled returns, $\mathbb{E}[r_t|r_T] = (1 - \alpha)\mu_t + \alpha r_T$, increases in today's market return r_T .*

Hypothesis 2. *(Recency effect) The strength of cued recall, measured by α , is decreasing in τ .*

Model results: simulation

Step 2: Simulation

- ▶ Assume that her predicted distribution of r_{T+1} is a weighted average of recalled distributions of past experiences:

$$f_{T+1} = \sum_{t=1}^{T-1} w_t f_t^q$$

- $w_t > 0$ and $\sum_{t=1}^{T-1} w_t = 1$

Model results: simulation

Step 2: Simulation

- ▶ Assume that her predicted distribution of r_{T+1} is a weighted average of recalled distributions of past experiences:

$$f_{T+1} = \sum_{t=1}^{T-1} w_t f_t^q$$

- $w_t > 0$ and $\sum_{t=1}^{T-1} w_t = 1$

Hypothesis 3. (*Return extrapolation*) Expected stock return for period $T + 1$, $\mathbb{E}(r_{T+1})$, is increasing in the return cue r_T .

Cued recall and belief formation

Survey Design

The *FreeRecall* block

FreeRecall

- ▶ Capture an episode of market movement that first comes to mind
 - motivated by the well-established experimental paradigm of free recall
- ▶ By “free,” we mean minimal guidance and conditions on what periods to be recalled
 - an investor always starts the survey with this block

The *FreeRecall* block

FreeRecall

- ▶ Capture an episode of market movement that first comes to mind
 - motivated by the well-established experimental paradigm of free recall
- ▶ By “free,” we mean minimal guidance and conditions on what periods to be recalled
 - an investor always starts the survey with this block
- ▶ Once an investor starts the block, we ask them to
 - “*first think about the overall stock market movement since you opened an account*”
 - then answer the following questions:
 - ① “*What period of market movement first came to your mind?*”
 - ② “*How much did the market (Shanghai Composite Index) move during this period?*”

The *ProbedRecall* block

ProbedRecall

- ▶ Ask investors to recall performance in the stock market over a certain period of time
- ▶ By “probed,” we mean these questions are designed with more elaborate conditions

The *ProbedRecall* block

ProbedRecall

- ▶ Ask investors to recall performance in the stock market over a certain period of time
- ▶ By “probed,” we mean these questions are designed with more elaborate conditions
- ▶ When an investor starts the block, we ask “*to the best of your recollection, what was the cumulative return rate of your equity investment over*
 - ① *last trading day?*”
 - ② *last month?*”
 - ③ *last year (in 2021)?*”
 - ④ *last five years?*”

The *Expectation* block

Expectation

- ▶ We follow the literature on survey expectations and use a standard methodology to measure investor expectations (Greenwood and Shleifer, 2014; Giglio et al., 2021)
 - horizon: 1-month and 1-year
 - about market return or about their own return

Other issues

- ▶ At the beginning of the survey, investors are explicitly instructed to use their memory and **not** to check on their phone
 - however, we do not observe if an investor does
 - most investors finish the survey within ten minutes
 - checking their account would lead to an attenuation bias

Other issues

- ▶ At the beginning of the survey, investors are explicitly instructed to use their memory and **not** to check on their phone
 - however, we do not observe if an investor does
 - most investors finish the survey within ten minutes
 - checking their account would lead to an attenuation bias
- ▶ Investors also need to go through a comprehension check to proceed

Other issues

- ▶ At the beginning of the survey, investors are explicitly instructed to use their memory and **not** to check on their phone
 - however, we do not observe if an investor does
 - most investors finish the survey within ten minutes
 - checking their account would lead to an attenuation bias
- ▶ Investors also need to go through a comprehension check to proceed
- ▶ We collect demographics and other information in a standard questionnaire
 - today we will mostly use them as control variables

Survey implementation

- ▶ We collaborated with one of the largest financial institution in China
 - randomized across 30 provinces and regions

Survey implementation

- ▶ We collaborated with one of the largest financial institution in China
 - randomized across 30 provinces and regions
- ▶ After basic filters, sample size $\approx 17\text{K}$ [▶▶ demo](#)
 - geographic distribution proportional to financial development
 - well-educated, wealthy investor sample
- ▶ After merging with transaction data $\approx 5\text{K}$ investors

Stylized Facts

Fact I: Free recall exhibits both recency and salience effects

Figure: Distribution of start and end month

Blue line: Shanghai Composite index

Black bar: recall frequency

Fact II: recalled returns are highly correlated with actual returns

- ▶ In *FreeRecall*, recalled episode return highly correlated with actual episode return ($\rho = 0.53$)
- ▶ In *ProbedRecall*, recalled own return highly correlated with actual own return at all horizons ($0.07 < \rho < 0.40$)

Bottom-line

- ▶ Respondents are indeed making a conscious effort in recall tasks

Testing the Model

Variation in returns

- ▶ The survey spans 6 weeks, during which the market exhibits mild yet still significant movement

Variation in returns

- ▶ The survey spans 6 weeks, during which the market exhibits mild yet still significant movement

- ▶ Within a day, we record the precise time when an investor begins to take the survey
 - intraday movements → different cues
- ▶ We also consider portfolio-level return for the merged sample (see paper)

Cued recall in *FreeRecall*: full-sample results

$$\widehat{MktRet}_i^{Free} = \beta_0 + \beta_1 MktRet_{t \rightarrow t+t_i} + X_i + \epsilon_i,$$

	<i>Recalled episode return</i>		
	Full		
Market return, today	0.32 (1.35)		-0.21 (1.49)
Market return, past month		-0.61 (0.53)	-0.57 (0.58)
Observations	3,443	3,612	3,443
Adjusted R^2	0.01	0.01	0.01

Discussion: results in the full sample

Possible reasons

- ① Recalled episodes in *FreeRecall* often capture dramatic events featuring large swings in asset prices
 - retrieving such events may require more dramatic cues
 - in a follow-up project, we ran a similar survey during more turbulent market periods and find stronger evidence of cued recall [▶▶ details](#)

Discussion: results in the full sample

Possible reasons

- ① Recalled episodes in *FreeRecall* often capture dramatic events featuring large swings in asset prices
 - retrieving such events may require more dramatic cues
 - in a follow-up project, we ran a similar survey during more turbulent market periods and find stronger evidence of cued recall [▶▶ details](#)
- ② High-frequency cues such as daily returns can only cue more recent experiences
 - consistent with Hypothesis 2
 - *temporal contiguity*: experiences that occur close together in time are associated to each other

Discussion: results in the full sample

Possible reasons

- ① Recalled episodes in *FreeRecall* often capture dramatic events featuring large swings in asset prices
 - retrieving such events may require more dramatic cues
 - in a follow-up project, we ran a similar survey during more turbulent market periods and find stronger evidence of cued recall [▶▶ details](#)
 - ② High-frequency cues such as daily returns can only cue more recent experiences
 - consistent with Hypothesis 2
 - *temporal contiguity*: experiences that occur close together in time are associated to each other
- ▶ We consider the subsample of investors recalling more recent episodes in *FreeRecall*

Cued recall in *FreeRecall*: subsample of recent recalls

$$\widehat{MktRet}_i^{Free} = \beta_0 + \beta_1 MktRet_{t \rightarrow t+t_i} + X_i + \epsilon_i,$$

	<i>Recalled episode return</i>

- ▶ a one-standard-deviation increase in the recalled own return
 - 0.9% increase in expected market return next year
 - 5.5% increase in expected own return next year

Additional properties

- ▶ Simulation exhibits horizon-dependence.
- ▶ Subjective recalled experience dominate objective actual experience in explaining expected future returns.
- ▶ A single variable based on recalled own return has similar explanatory power, measured by R-squared, than that of an

Discussion: alternative explanations

- ▶ We obtain very similar relationships between memories and forecast errors
 - memory does not only drive return expectations themselves, but also contribute to forecast errors at the individual level

Discussion: alternative explanations

- ▶ We obtain very similar relationships between memories and forecast errors
 - memory does not only drive return expectations themselves, but also contribute to forecast errors at the individual level
- ▶ We do not claim causality
 - but the strong and robust correlation between memories and beliefs is highly suggestive of a memory-based channel of belief-formation

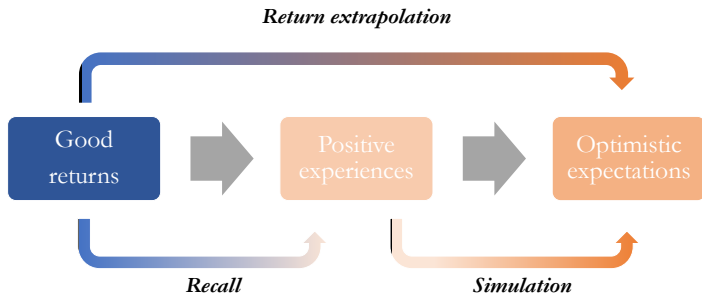

Discussion: alternative explanations

- ▶ We obtain very similar relationships between memories and forecast errors
 - memory does not only drive return expectations themselves, but also contribute to forecast errors at the individual level
- ▶ We do not claim causality
 - but the strong and robust correlation between memories and beliefs is highly suggestive of a memory-based channel of belief-formation
- ▶ We discuss several alternative explanations
 - 1 anchor effects [▶ details](#)
 - 2 click-through behavior [▶ details](#)
 - 3 motivated beliefs [▶ details](#)
 - 4 external validity [▶ details](#)

Cued recall and return extrapolation

Cued recall and return extrapolation

- ▶ *Key implication:* Controlling for memories should weaken or eliminate the positive correlation between past returns and expectations

Conclusion

Conclusion

- ▶ There are growing interests in understanding the role of memory in driving beliefs and choices

Conclusion

- ▶ There are growing interests in understanding the role of memory in driving beliefs and choices
- ▶ We contribute to this literature by bringing new evidence from the field
 - survey a large representative sample of retail investors to elicit their memories
 - merging the survey data with administrative data of transactions

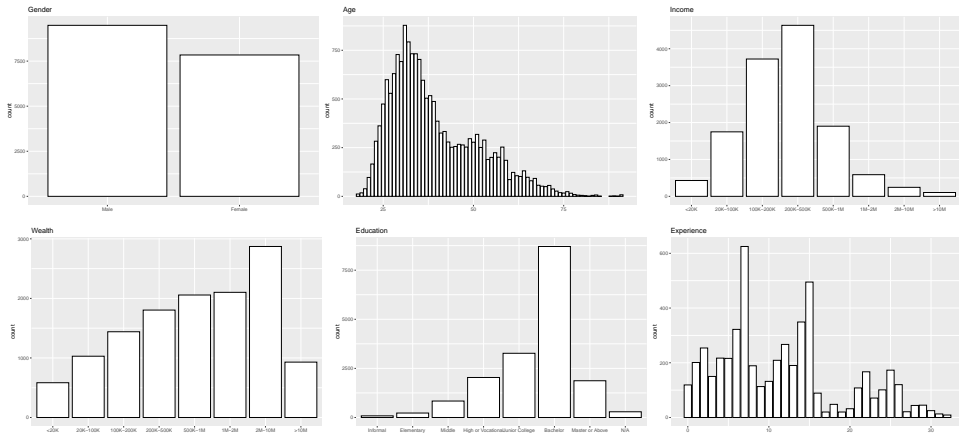

Conclusion

- ▶ There are growing interests in understanding the role of memory in driving beliefs and choices
- ▶ We contribute to this literature by bringing new evidence from the field
 - survey a large representative sample of retail investors to elicit their memories
 - merging the survey data with administrative data of transactions
- ▶ Main takeaways:
 - ① what's on the mind of an investor is heavily influenced by what is going on in the market
 - ② past experiences emerge at a given moment do affect belief formation
 - ③ return extrapolation can be microfounded by cued recall

Thank you!

▶▶ back

Model details

- ▶ One particular formulation of the return-cued PDF is by assuming that the current return, r_t , is a noisy signal of recalled return in the simulation process:

$$r_t = r_t + \epsilon \sqrt{t-t} = r_t + \epsilon_{t,t}$$

where ϵ is normally distributed $\epsilon \sim N(0, \sigma_\epsilon^2)$

- ▶ The cued PDF of simulated returns is the conditional distribution of $r_t|r_t$, given by

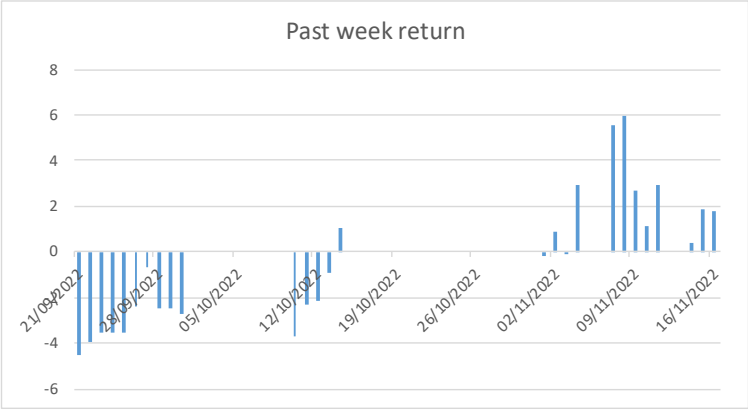

$$r_t|r_t \sim N\left(\frac{\sigma_\epsilon^2(t-t)}{\sigma_t^2 + \sigma_\epsilon^2(t-t)}\mu_t + \frac{\sigma_t^2}{\sigma_t^2 + \sigma_\epsilon^2(t-t)}r_t, \frac{(t-t)\sigma_t^2\sigma_\epsilon^2}{\sigma_t^2 + \sigma_\epsilon^2(t-t)}\right)$$

- ▶ This is when s^* takes the following form:

$$s^*(r_t, r_t) = \frac{\sigma_t}{\sigma_q} \exp\left(-\frac{1}{2} \frac{(r_t - r_t)^2}{(t-t)\sigma_\epsilon^2} + \frac{(\mu - r_t)^2}{2(\sigma^2 + (t-t)\sigma_\epsilon^2)}\right)$$

where $\sigma_q^2 = \frac{(t-t)\sigma_t^2\sigma_\epsilon^2}{\sigma_t^2 + (t-t)\sigma_\epsilon^2}$ [▶ back](#)

Follow up: market conditions
